To all my students, past, present, and future!

Preface

The *Encyclopedia of Computer Graphics and Games* (ECGG) is an authoritative reference work covering the history, technologies, and trends of computer graphics and games catered to industry professionals and academic communities worldwide. The breadth and depth of topics covered by the encyclopedia benefit a wide diversity of readers including researchers, practitioners, teachers, and students who seek general as well as specific knowledge in computer graphics and games.

Los Angeles, USA — Newton Lee
November 2023

Acknowledgements

The *Encyclopedia of Computer Graphics and Games* (ECGG) is a labor of love by more than 365 contributing authors, peer reviewers, academic and industry co-chairs, editorial board members, and volunteers. I would like to extend my heartfelt thanks to everyone including Springer Nature editors and project coordinators for making this encyclopedia a reality.

List of Topics

3D Visualization

3D Modelling Through Photogrammetry in Cultural Heritage
3D Printing, History of
3D Visualization Interface for Temporal Analysis of Social Media
3D-Rendered Images and Their Application in the Interior Design
Deep Learning Algorithms for 3D Reconstruction
Tactile Visualization and 3D Printing for Education
Technologies for the Design Review Process

Animation

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design
Animation and Neurocinematics: Visible Language of E-motion-S and Its Magical Science
Challenges Facing the Arab Animation Cinema
Character Animation Scripting Environment
Exploring Innovative Technology: 2D Image Based Animation with the iPad
Motion Matching: Data-Driven Character Animation Systems
Pipeline of 2D Vector Animation in Television Series
Preserving the Collective Memory and Re-creating Identity Through Animation
Teaching Computer Graphics by Application
Vector Graphics

Animation(Facial)

Face Beautification in Antiage

Applying Artificial Intelligence to Virtual Reality and Intelligent Virtual Environments

3D Room Layout System Using IEC (Interactive Evaluational Computation)
Emotion-Based 3D CG Character Behaviors
Genetic Algorithm (GA)-Based NPC Making

Art and Design

Artistic Data Visualization in the Making
Color: Pixels, Bits, and Bytes
Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being
Imagineering Ceramic Pottery Using Computer Graphics

Artificial Intelligence

Automated Game Design Testing Using Machine Learning
Character Artificial Intelligence
Classical Learning Method in Digital Games
Computer Games and Artificial Intelligence
Computer Go
Constructing Game Agents Through Simulated Evolution
Game Player Modeling

Machine Learning for Computer Games
Meta Artificial Intelligence and Artificial Intelligence Director
Monte-Carlo Tree Search
Navigation Artificial Intelligence
Overview of Artificial Intelligence
Quality Assurance-Artificial Intelligence
RTS AI Problems and Techniques
Skull and Roses Card Game
StarCraft Bots and Competitions
World Representation in Artificial Intelligence

Audio

Adaptive Music
Audio and Facial Recognition CAPTCHAs for Visually Impaired Users
Audiogame
Dynamic Music Generation: Audio Analysis-Synthesis Methods
Emotional Congruence in Video Game Audio
Overview of Virtual Ambisonic Systems
Procedural Audio in Video Games
Spatial Audio and Sound Design in the Context of Games and Multimedia

Augmented Reality

3D Selection Techniques for Distant Object Interaction in Augmented Reality
Augmented and Gamified Lives
Augmented Learning Experience for School Education
Augmented Reality Entertainment: Taking Gaming Out of the Box
Augmented Reality for Human-Robot Interaction in Industry
Augmented Reality for Maintenance
Augmented Reality in Image-Guided Surgery
Augmented Reality Ludo Board Game with Q-Learning on Handheld
Conceptual Model of Mobile Augmented Reality for Cultural Heritage
Enhanced Visualization by Augmented Reality
Gamification and Social Robots in Education
History of Augmented Reality
Integrating Virtual Reality and Augmented Reality into Advertising Campaigns: History, Technology, and Future Trends
Interacting with a Fully Simulated Self-Balancing Bipedal Character in Augmented and Virtual Reality
Interaction with Mobile Augmented Reality Environments
Interactive Augmented Reality to Support Education
Key Early Verticals: Challenges and Limitations in Implementation of Augmented Reality
Life-Size Telepresence and Technologies
Live Texture Mapping in Handheld Augmented Reality Coloring Book
Mixed Reality
Potential of Augmented Reality for Intelligent Transportation Systems
Virtual Reality and Robotics

Augmented Reality and Virtual Reality

Artificial Reality Continuum
Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface
Collaborative Environments for Augmented and Virtual Reality Applications
Color Detection Using Brain Computer Interface
Construction Management Processes in a Digital Built Environment, Modelling
Digital Images Using Heuristic AdaBoost Haar Cascade Classifier Model, Detection of Partially Occluded Faces
Engaging Dogs with Computer Screens: Animal-Computer Interaction
Fingerprint Verification Based on Combining Minutiae Extraction and Statistical Features
Gaming Control Using BCI
Immersive Technologies for Accessible User Experiences
Immersive Visualizations Using Augmented Reality and Virtual Reality
Interactive Augmented Reality Pop-Up Book with Natural Gesture Interaction for Handheld
Object Manipulation Using Real Hand Gesture for Augmented Reality Interior Design
Position-Aware 3D Facial Expression Mapping Using Ray Casting and Blendshape

Smart Calibration Between RGB-D and Thermal Cameras for ROI Detection and Tracking in Physiological Monitoring
Tabletop Storytelling
Tracking Techniques in Augmented Reality for Handheld Interfaces
Virtual Human for Assisted Healthcare: Application and Technology
Virtual Reality Proton Beam Therapy Unit: Case Study on the Development
Volumetric Filmmaking

Cinematics

Movie-Making of Spatiotemporal Dynamics in Complex Systems
Postproduction in Game Cinematics

Computer Vision

American Sign Language Detection
Experiential Media: Using Machine Vision and Sensor-Input to Create Dynamic Real-Time Generated Media
Fall Risk Detection in Computer Vision
Healthcare Robots with Islamic Practices
Locomotion and Human Tracking in Healthcare Robots

Data Visualization

2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making
Cognitive Processing of Information Visualization
Indigenous Knowledge for Mental Health, Data Visualization
Indigenous Language Revitalization with Stories and Games
Mixed Reality and Immersive Data Visualization
Multivariate Visualization Using Scatterplots
Scalable Techniques to Visualize Spatiotemporal Data
Stress Reduction, Relaxation, and Meditative States Using Psychophysiological Measurements Based on Biofeedback Systems via HRV and EEG
Tensor Field Visualization

Education

Cross-cultural Game Studies
PBL-Based Industry-Academia Game Development Education

Engine Architecture

Game Engine
Game Loop and Typical Implementation
Game Physics Engine, Overview
Interactive Computer Graphics and Model-View-Controller Architecture
Panda3D
Physical, Virtual, and Game World Persistence
Unity, a 2D and 3D Game Engine
Unreal Engine, a 3D Game Engine
Virtual World, a Definition Incorporating Distributed Computing and Instances

Game and other Media

Animal Crossing: A Causal Game
Anti-phishing Attacks in Gamification
Assassin's Creed, an Analysis
Bayonetta 2, an Analysis
Call of Duty Franchise, an Analysis
Children Privacy Protection
Children's Games, from Turtle to Squirtle
Computer Games and the Evolution of Digital Rights
Computer Games in Education
Counter-Strike Global Offensive, an Analysis
Dark Souls III, an Analysis
Dark Souls RPG Through the Lens of Challenge
Destiny and Destiny 2, an Analysis of an FPS
Digital Games for Animals
Diversity in Gaming and the Metaverse
Dōjin Game
Facial Recognition and Emotion Detection in Environmental Installation and Social Media Applications
Fantasy XVI Online, a Massively Multiplayer Online Role-Playing Game
Fire Emblem Fates, Conquest
First-Person Shooter Games, a Brief History
Five Nights at Freddy's, a Point and Click Horror Game

Fortnite: A Brief History
Games and the Magic Circle
Gamification of Modern Society: Digital Media's Influence on Current Social Practices
Gardenscapes and Homescapes, Casual Mobile Games
God of War (2018), an Action-Adventure Game
God of War, an Analysis
Hypermedia Narrative as a Tool for Serious Games
Itch.io, History of
King of Fighters, a Brief History
Kingdom Hearts (2002): An Analysis
Mario Kart, an Analysis of Its Absence from Esports
NBA 2K, a Brief History
NFT Games
On Computer Games About Cooking
Origin of Games
Overwatch: Team-Based Multiplayer First-Person Shooter Game
Pervasive Games
Pokémon and World Championships
Professional Call of Duty Player Matthew "Nadeshot" Haag: An e-Sports Case Study
Public Health Education via Computer Games
Rocket League: An Analysis
Smart Toys
Social-, Mobile-, and Multi-Player-Games and Their Impact on Today's Online Entertainment Industry
Sociality of Digital Games
Sonic Adventure 2, an Analysis
Speedrunning
Speedrunning in Video Games
Star Wars Battlefront (2004), an Analysis
STEM Learning Through Video Games
Super Mario Galaxy: An Overview
Super Smash Bros. Ultimate and E-sports
Super Smash Bros.: A Brief History
The Elder Scrolls V Skyrim
Toy Computing
Video Game Culture in Cape Town, South Africa
World of Tanks, MMO Strategy Freemium Game
World of Warcraft, a MMORPG with Expansions

Game Design and Development

3D Game Asset Generation of Historical Architecture Through Photogrammetry
3D Puzzle Games in Extended Reality Environments
Academic and Video Game Industry "Divide"
Among Us and Its Popularity During COVID-19 Pandemic
Analog Prototyping for Digital Game Design
Animal Crossing: New Horizons and Its Popularity During COVID-19 Pandemic
Challenge-Based Learning in a Serious Global Game
Comic Arts in Games, Asset Production, and Rendering
Dark Souls Through the Lens of Essential Experience
Dead Space Through the Lens of Resonance
Design Framework for Learning to Support Industry 4.0
Design of Alienation in Video Games
Domain-Specific Choices Affecting Design Effort in Gamification
Educational Game Abzû and the Lens of Fun Learning
Emotion in Games
Game Design and Emotions: Analysis Models
Game Development Leadership Tips
Game Prosumption
Game Thinking X Game Design Thinking
Game Writer's Dilemma: Context vs. Story
Game-Based Interventions in Public Health: Exploiting the Engaging Factor of Gameplay
Games and Active Aging
Games in Science
Gamification
Gamification and Serious Games
Gamification Ethics
Gamification in Crowdsourcing Applications
Hades: An Analysis
Hearthstone: A Collectable Card Game Through the Lens of Problem Solving
Incremental Games
Indie Game

Legend of Zelda Breath of the Wild and the Lens of Curiosity
Madden NFL and Infinite Inspiration
MEEGA+, Systematic Model to Evaluate Educational Games
Motion Planning in Computer Games
Narrative Design
Narrative in Video Games
New Super Mario Bros. Wii, an Analysis
Nursing Education Through Virtual Reality: Bridging the Gap
Online Gaming Industry Evolution, Monetization, and Prospects
Online Players: Engagement, Immersion, and Absorption Across Secondary Worlds
Parasocial Phenomena in Video Games
Persona 3 and the Lens of Surprise
Player Experience, Design and Research
Player Personas and Game Choice
Political Game Design
Post-Digital Graphics in Computer Games
Principle Structure to Create a 2D Game Level Editor
Protection Korona: A Game Design on Covid-19
Psychological Game Design
Query-by-Gaming
Redesigning Games for New Interfaces and Platforms
Rehabilitation Games
Resident Evil 2, History of
ROP-Skill System: Model in Serious Games for Universities
Secure Gaming: Cheat-Resistant Protocols and Game History Validation
Semiotics of Computer Games
Serious Online Games for Engaged Learning Through Flow
Spatio-temporal Narrative Framework for Architecture in Video Games
Strategies for Design and Development of Serious Games: Indian Perspective
Symbolic Planning in Computer Games
The Sims Franchise, a Retrospective of Racial Representation and Skin Tones
Timed Automata for Video Games and Interaction
Transformational Games
Underground Design of Kaizo Games
Video Game Storytelling Fundamentals: Setting, Power Status, Tone, and Escalation
Video Game Trolls and Dopamine Withdrawal
Videogame Engagement: Psychological Frameworks
Visual Accessibility in Computer Games
Visual Novel

Holography

Holography as an Architectural Decoration
Holography, History of
Image Quality Evaluation of a Computer-Generated Phase Hologram

Interaction

Biosensing in Interactive Art: A User-Centered Taxonomy
Computer Games for People with Disability
Player-Avatar Link: Interdisciplinary Embodiment Perspectives
Video Games and Accessibility: A Case Study of The Last of Us II

Miscellaneous

Contemporary Computer Shogi
Loot Boxes: Gambling-Like Mechanics in Video Games
Minkowski-Lorentz Spaces Applications: Resolution of Apollonius and Dupin Problems
Mobile Persuasive Applications
Player Abusive Behavior Detection
Puyo Puyo
Shadow Shooter: All-Around Game with e-Yumi 3D
Theory of Minkowski-Lorentz Spaces
Underwater Enhanced Detail and Dehaze Technique (UEDD) for Underwater Image Enhancement

Modeling and Texturing

B-Splines
Constrained Edges and Delaunay Triangulation
Delaunay Triangulation

Modeling and Mesh Processing for Games
Pencils of Spheres in the Minkowski-Lorentz Spaces
Planetary Generation in Games
Poisson-Disk Sampling: Theory and Applications
Shape Deformation Models
Sketch-Based Posing for 3D Animation
Spheres, AABB, and OOBB as Bounding Volume Hierarchies
The New Age of Procedural Texturing
UV Map Generation on Triangular Mesh

Networked Games

Area of Interest Management in Massively Multiplayer Online Games
Client/Server Gaming Architectures
Cloud for Gaming
Cognitive Psychology Applied to User Experience in Video Games
Detecting and Preventing Online Game Bots in MMORPGs
Disney Toontown Online, a Massively Multiplayer Online Role-Playing Game
Distributed Simulation and Games
Game Bot Detection on Massive Multiplayer Online Role-Playing Games (MMORPGs) Systems
Griefing in MMORPGs
IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games
Mobile Cloud Gaming
Online Gaming Architectures
Online Gaming Scalability
Peer-to-Peer Gaming
Toxic Behaviors in Online Gaming

Open-Source Code

Open Source 3D Printing, History of

Physics and Simulation

Bounding Volume Hierarchies for Rigid Bodies
Cellular Automata Methods
Collision Detection
Computational Steering for Computational Fluid Dynamics
Crowd Evacuation Using Simulation Techniques
Crowd Simulation
Fluid Simulation
Lattice Boltzmann Method for Diffusion-Reaction Problems
Lattice Boltzmann Method for Fluid Simulation
Lattice Gas Cellular Automata for Fluid Simulation
Position Based Dynamics
Simulation and Comparison of AODV and DSDV Protocols in MANETs
Simulation of Emotional Crowd and Applications

Platform

Game Venues and Platforms
Ludii General Game System for Modeling, Analyzing, and Designing Board Games

Rendering

High-Performance Many-Light Rendering
Ray Tracing in Video Games
Rendering Equation

User Interface

Automated Image Captioning for the Visually Impaired
Data Gloves for Hand and Finger Motion Interactions
Decoupling Game Tool GUIs from Core Editing Operations
Game Interface: Influence of Diegese Theory on the User Experience
Human Interaction in Machine Learning (ML) for Healthcare
Plug-in-Based Asset Compiler Architecture
Tangible Surface-Based Interactions
Unified Modeling Language (UML) for Sight Loss
User Interface (UI) in Semiautonomous Vehicles

Virtual Reality

3D Avatars in Virtual Reality Experience
Accessibility of Virtual Reality for Persons with Disabilities
Collaborative Engineering and Virtual Prototyping Within Virtual Reality

Cybersickness
Deep Reinforcement Learning in Virtual Environments
Educational Virtual Reality Game Design for Film and Animation
EEG as an Input for Virtual Reality
Everyday Virtual Reality
Eye Tracking in Virtual Reality
Foundations of Interaction in the Virtual Reality Medium
History of Virtual Reality
Immersive Auralization Using Headphones
Immersive Technologies for Medical Education
Immersive Virtual Reality Serious Games
Information Presentation Methods in Virtual Reality
Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology
Locomotion in Virtual Reality Video Games
Making Virtual Reality (VR) Accessible for People with Disabilities
Mindfulness, Virtual Reality, and Video Games
Mixed Reality, Gamified Presence, and Storytelling for Virtual Museums
Multi-user Virtual Environments for Education
Natural Walking in Virtual Reality
Origin of Virtual Reality
Perceptual Illusions and Distortions in Virtual Reality
Presence and Immersion in Virtual Reality
Raycasting in Virtual Reality
Redirected Walking in Virtual Reality
Social Virtual Reality
Sonic Interactions in Virtual Environments
Sound Spatialization
Spatial Perception in Virtual Environments
Storytelling in Virtual Reality
Substitutional Reality
Training Spatial Skills with Virtual Reality and Augmented Reality
Trustworthy Embodied Virtual Agents
Uncanny Valley in Virtual Reality
User Acoustics with Head-Related Transfer Functions
User-Centered Design and Evaluation Methodology for Virtual Environments
Virtual Hand Metaphor in Virtual Reality
Virtual Pointing Metaphor in Virtual Reality
Virtual Reality Applications in Education
Virtual Reality as New Media
Virtual Reality Exercise and Rehabilitation
Virtual Reality Game Engines
Virtual Reality Retailing
Virtual Reality Stereo Post-Conversion After Effects Workflow
Virtual Reality System Fidelity
Virtual Reality Systems, Tools, and Frameworks
Virtual Reality Therapy
Virtual Reality: A Model for Understanding Immersive Computing
Virtual Reality-Based Daily Scrum Meetings

About the Editor

Newton Lee is the founding president of the 501(c)(3) nonprofit Institute for Education, Research, and Scholarships based in Los Angeles, California, a former Disney and Bell Labs engineer, and a 2021 graduate of the FBI Citizens Academy.

Serving as an FBI Ambassador, Prof. Lee expounds on social media, campus safety, student mental health, cybersecurity, and counterterrorism as portrayed in the highly acclaimed Total Information Awareness book series published by Springer Nature. The Total Information Awareness trilogy has garnered rave reviews from *Newsweek*, *The Daily Beast*, *ACM Computing Reviews*, *AdWeek*, and *Choice Magazine*, among others. Veteran Staff Sergeant Andrew Price of the United States Air Force (USAF) remarked, "I am inspired by the prospect of world peace. I'd fully recommend following the author's steps, reaching beyond our borders, making friends outside our norm, and helping to foster world peace and a better tomorrow."

Prof. Lee has co-developed over 100 online games at The Walt Disney Company, and 12 bestselling and award-winning interactive titles including The Lion King Animated Storybook and Winnie the Pooh and the Honey Tree that were featured in the *Billboard* Magazine. He has also executive produced original songs that have played on American Idol and charted on US Billboard, UK Music Week, and US iTunes HOT 100 (Electronic).

He earned a B.S. and M.S. in Computer Science from Virginia Tech as well as an A.S. in Electrical Engineering and an honorary doctorate in Computer Science from Vincennes University. He has

been honored with a Michigan Leading Edge Technologies Award, two community development awards from the California Junior Chamber of Commerce, and four volunteer project leadership awards from The Walt Disney Company.

2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making

Anna Yankovskaya
Tomsk State University of Architecture and Building, Tomsk, Russia

Synonyms

2-Simplex prism; Cognitive graphics tool; Decision-making; Geoinformation system; Intelligent dynamic system; Justification; n-simplex

Definition

The following definitions from the papers (Yankovskaya 2011; Yankovskaya et al. 2015a) are used:

A cognitive graphics tool (CGT) visually reflects a complex object, phenomenon, or process on a computer screen, enabling the users to form a new decision, idea, or hypothesis based on the visuals.

2-Simplex is an equilateral triangle.

3-Simplex is a regular tetrahedron.

2-Simplex prism is a triangular prism which has identical equilateral triangles (2-simplexes) in its bases.

© Springer Nature Switzerland AG 2024
N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

The height of the 2-simplex prism (Yankovskaya et al. 2015a) in intelligent dynamic systems corresponds to the dynamic process time interval under consideration. It is divided into a number of time intervals. The number of time intervals corresponds to the number of diagnostic or predictive decisions.

The distance between two adjacent 2-simpleces is proportional to the time interval between adjacent 2-simpleces.

In this case the distance between two adjacent 2-simpleces corresponds to the distance between two points on a map.

Learning axis is an independent direction of student evolution, e.g., theory knowledge level, ability to practical tasks solving, ability of electric circuit design, and research.

Test result is a set of coefficients, numerically representing the student's assessment achieved. Each coefficient corresponds to a particular learning axis.

Prediction result is a set of coefficients, numerically representing the student's assessment which he is likely to achieve in a preassigned time interval.

Introduction

Cognitive graphics tool (CGT) was developed as part of AI research in the 1980s of the twentieth century in the works of Pospelov (1992) and Zenkin (1991). A large number of CGT have been created and developed, including cognitive maps (Axelrod 1976), cognitive graphics system (Albu and Khoroshevskiy 1990), medical CGT (Kobrinskiy 1996), radar plots (Saary 2008), Chernoff faces (Raciborski 2009), the ternary diagram (Wang et al. 2012), 2-simplex (Yankovskaya 2011), and others (Yankovskaya et al. 2015a; Yankovskaya 2017). CGT allows representing the content of the object or process under investigation on a computer screen. CGT visually and clearly reflects the essence of a complex object (phenomenon, process) and is also capable of providing a fundamentally new decision (idea, hypothesis). An important feature of CGT is targeted influence on the intuitive imaginative thinking mechanisms.

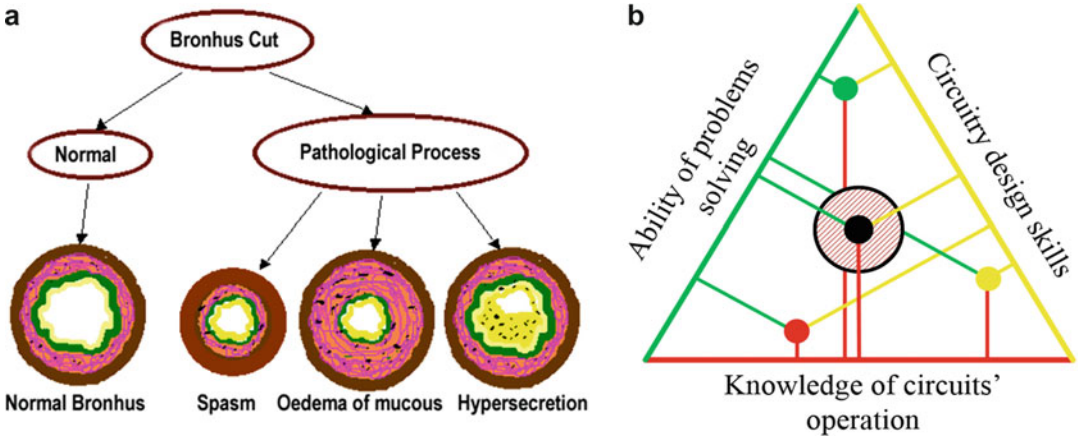
Cognitive graphics tools are used in a variety of intelligent systems for analysis of information structures of knowledge and data, revealing of different kinds of regularities in data and knowledge, and decision-making and its justification. Possible areas of application are medicine (diagnosis of diseases, treatment and preventive measures, rehabilitation of patients as well as solving organizational and managerial problems), education, geology, engineering, electronics, sociology, psychology, psychiatry, ecobiomedicine, ecogeology, etc. Dynamism represented by CGT can effectively reflect the dynamics of the patterns of objects under investigation in time.

Problem Background and Mathematical Basics of Intelligent Systems Construction

We suggest the following classifications of CGT by ways of representation (Yankovskaya and Galkin 2009; Yankovskaya 2011):

1. Naturalistic CGT, familiar graphic images of real objects. For example, visualization of tree data structure of pathological processes in bronchus (bronchial asthma, Fig. 1a).
2. Abstract CGT, CGT that does not have a mapping in the ordinary reality. For example, visualization of current level of students' knowledge by applying 2-simplex (Fig. 1b).

We use test pattern recognition to create the intelligent systems (Yankovskaya 2011), based on nontraditional (unusual) matrix method of data and knowledge representation; deep optimizing logic-combinatorial transformations in feature space; logic-combinatorial and logic-probabilistic, logic-combinatorial-probabilistic, and genetic methods of test pattern recognition; methods of complex decision-making; cognitive



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 1 Examples of naturalistic-based CGT (**a**) and CGT that does not have mapping in the ordinary reality (**b**)

2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 2 Matrix model for the data and knowledge representation

$$Q=\begin{array}{c}\begin{matrix}z_1 & z_2 & z_3 & z_4 & z_5 & z_6 & z_7 & z_8 & z_9 & z_{10} & z_{11}\end{matrix}\\ \begin{bmatrix}1&4&6&3&2&2&1&2&3&4&1\\4&4&5&2&3&2&7&8&3&4&1\\3&4&5&3&3&2&4&5&3&4&1\\3&4&4&1&4&4&2&3&1&5&1\\2&4&2&1&6&3&4&5&2&3&1\\2&4&5&1&3&-&4&3&1&2&1\\1&4&3&2&5&2&1&2&3&4&1\\3&4&2&2&6&2&2&3&3&2&1\\5&4&2&2&6&3&5&6&2&4&1\\4&4&6&1&2&5&5&6&1&4&2\end{bmatrix}\end{array}\begin{matrix}1\\2\\3\\4\\5\\6\\7\\8\\9\\10\end{matrix}\quad R=\begin{array}{c}\begin{matrix}k_1 & k_2\end{matrix}\\ \begin{bmatrix}1&2\\1&2\\1&2\\2&1\\2&1\\2&1\\1&3\\1&3\\3&2\\3&2\end{bmatrix}\end{array}\quad R'=\begin{bmatrix}1\\1\\1\\2\\2\\2\\3\\3\\4\\4\end{bmatrix}$$

means of decision-making; and justification of decision-making results.

We use unusual matrix model (Yankovskaya 2011) for the data and knowledge representation, example of which is given in Fig. 2.

$\boldsymbol{Q}$ – integer descriptions matrix.

$z_1, z_2, \ldots, z_{11}$ – characteristic features.

$\boldsymbol{R}$ – integer distinguishing matrix.

k_1, k_2 – classification features.

$\boldsymbol{R}'$ – one-column matrix whose elements are the numbers of patterns. Each pattern is associated with the final decision.

Rows of $\boldsymbol{Q}$ are mapped to objects from learning sample of a problem field.

Columns of $\boldsymbol{Q}$ are mapped to characteristic features, which describe each object.

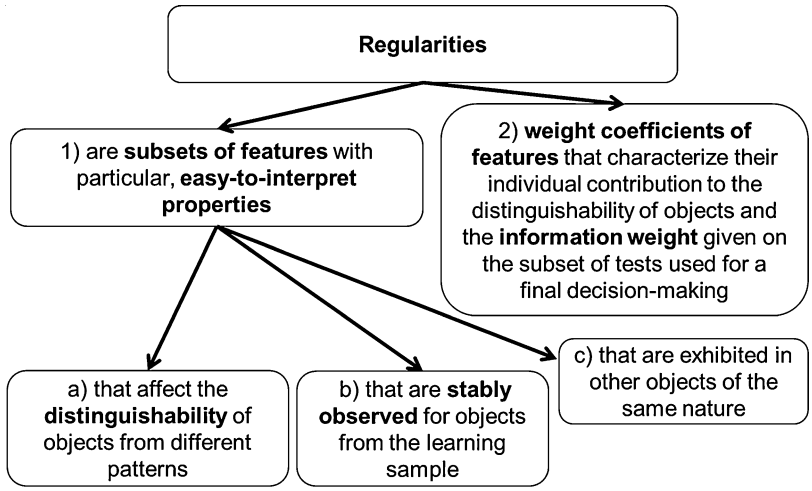
The element q_{ij} of the matrix $\boldsymbol{Q}$ determines the value j-th feature for i-th object if the value is defined and "–" if the value is undefined.

Each row of $\boldsymbol{R}$ is corresponded to the row of the matrix $\boldsymbol{Q}$ having the same index.

Columns of $\boldsymbol{R}$ are corresponded to distinguishing levels that represent classification features.

The set of all nonrepeating rows of the matrix $\boldsymbol{R}$ is compared to the number of selected patterns presented by the one-column matrix $\boldsymbol{R}'$.

The distinguishing matrices can be of three types (***R1***, ***R2***, and ***R3***). The rows of $\boldsymbol{Q}$ are put in correspondence with the rows of ***R1***, ***R2***, and ***R3*** and the levels of distinguishing (classification) features, with the columns of these matrices. ***R1***



Regularities
1) are **subsets of features** with particular, **easy-to-interpret properties**
2) **weight coefficients of features** that characterize their individual contribution to the distinguishability of objects and the **information weight** given on the subset of tests used for a final decision-making
a) that affect the **distinguishability** of objects from different patterns
b) that are **stably observed** for objects from the learning sample
c) that are exhibited in other objects of the same nature

2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 3 A block diagram of regularities definition

represents the included classification mechanisms. ***R2*** determines the sequence of actions which must be performed for each object. ***R3*** represents independent classification mechanisms corresponding, for instance, to the opinions of different experts.

The matrix of transition ***P*** (Yankovskaya et al. 2001; Yankovskaya 2011) is intended for the representation of dynamic knowledge about the investigated objects. Its rows are associated with the rows of ***Q***, and columns are associated with the instants (intervals) of time or control actions (Fig. 2).

The weight coefficients of the features characterizing their individual contribution to the distinguishability of objects from certain patterns (Yankovskaya 2011) and the information weight defined on the subset of tests used for a final decision-making (Yankovskaya 2011) with use the definition from Zhuravlev and Gurevitch (1990) is also regarded as regularities.

The following approaches are used when revealing regularities (Yankovskaya 2011): (1) with the construction of the irredundant matrix of implications; (2) with the partial construction of the irredundant matrix of implications; and (3) without the construction of the irredundant matrix of implications.

An irredundant matrix of implications ($\boldsymbol{U}'$) is constructed on the base of matrices ***Q*** and ***R*** and defines distinguishability of objects from different patterns (classes at the fixed mechanism of classification). The rows of $\boldsymbol{U}'$ are associated with characteristic features, and its columns, with the results of comparison of all possible pairs, pattern–pattern, object–pattern, and object–object, from different patterns.

A diagnostic test (DT) is a set of features that distinguishes any pair of objects that belong to different patterns and constructed on the base of irredundant implication matrix with application of logical-combinatorial algorithms (i.e., column coverings findings).

The DT is called "unconditional" if all features of the investigated object included in test are used simultaneously in decision-making process.

Decision-making on belonging of object under study to one or another pattern for every irredundant unconditional DT (IUDT) is performed out with use of threshold value of conditional degree of proximity of the object under study to the patterns.

Mixed DT (MDTs) present a new paradigm of development of intelligent systems based on test methods of pattern recognition (Yankovskaya 1996).

MDT is a compromise between unconditional and conditional components which are used for decision-making in intelligent systems as well as in blended education and training.

Respondent is a person participating in learning and testing.

Definition of a membership object x under study to pattern k is defined based on the coefficient of conditional degree of proximity (a_k) of object under study to the pattern (class) k, calculated by the formula (1):

$$a_k = \frac{S_k^x}{S_k},$$

where x – object under study

k – pattern (class),
S_k – coefficient of interclass similarity (similarity of objects inside the pattern (class)),
S_k^x – coefficient of similarity object x under study with pattern (class) k.

The rules for decision-making are constructed using coefficients of conditional degree of proximity a_i (Yankovskaya 2011).

Applied intelligent system is constructed on the base of intelligent instrumental software (IIS) IMSLOG (Yankovskaya et al. 2003). Purposes of IIS IMSLOG are formation of knowledge about objects in concrete problem or interdisciplinary area; regularities revealing in data and knowledge; decision rules construction on the basis of revealed regularities; recognition of object under investigation; and decision-making and its justification with CGT.

Mathematical Basis for Construction of Cognitive Graphics Tools

Theorem for the Construction of a Cognitive Graphics Tool n-Simplex

In 1991, Yankovskaya (1991), it was proposed using cognitive graphics tool 2-simplex for decision-making about object under investigation in the characteristic feature space to a certain pattern in intelligent systems for decision-making.

Theorem Suppose $a_1, a_2, \ldots, a_{n+1}$ is a set of simultaneously non-zero numbers where n is the dimension of a regular simplex. Then, there is one and only one point that following condition $h_1: h_2: \ldots: h_{n+1} = a_1: a_2: \ldots: a_{n+1}$ is correct, where h_i ($i = 1, 2, \ldots, n+1$) is the distance from this point to the i-th side (Yankovskaya 1991).

Coefficient h_i, ($i = 1, 2, \ldots, n+1$) represents the degree of conditional proximity of the object under investigation to the i-th pattern. The advantage is that n-simplex possesses the property of the constancy of the sum of distances (h) from any point to each side and the property of ratios preservation $h_1: h_2: \ldots: h_{n+1} = a_1: a_2: \ldots: a_{n+1}$.

The main function of n-simplex is a representation of an investigated object disposition among other objects of a learning sample (Yankovskaya 2011).

Construction of Cognitive Graphics Tools: 2-Simplex, 3-Simplex, and 2-Simplex Prism

We construct CGT 2-simplex and 3-simplex to visualize objects of 3 (4) patterns and the object under investigation using the formulas (1) given below.

For 2-simplex (3-simplex), distances h_1, h_2, and h_3 (h_1, h_2, h_3, h_4) are calculated on the basis of coefficients a_i and normalization operation from the following relations:

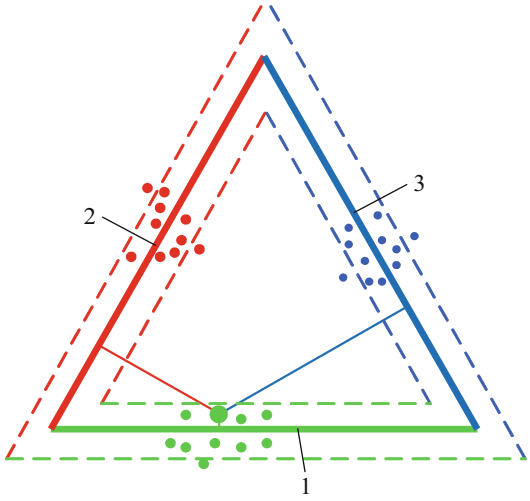
For 3-simplex distances h_1, h_2, h_3, and h_4 are calculated on the basis of coefficients a_i and normalization operation from the following relations:

$$\begin{cases} h = \sum_{i=1}^{4} h_i \\ h = \alpha \sum_{i=1}^{4} a_i \\ \frac{h_1}{a_1} = \frac{h_2}{a_2} = \frac{h_3}{a_3} = \frac{h_4}{a_4} \end{cases} \quad (1)$$

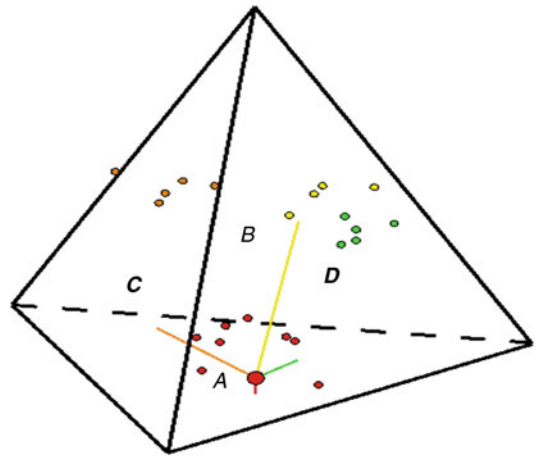
by the formula

$$h_i = \frac{h \cdot a_i}{\sum_{i=1}^{4} a_i} \quad (2)$$

Edges of 2-simplex (equilateral triangle edges), shown in Fig. 1b, are associated with three patterns (classes); the circle with big radius is the investigated object, and small circles are sample objects. Each pattern corresponds with some color. The distance from an object to a side is directly proportional to the object proximity to the pattern



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 4 2-Simplex with learning sample objects and the object under investigation



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 5 3-Simplex with learning sample objects and the object under investigation

corresponding to the side. The distance for the investigated object is displayed as color perpendicular lines to 2-simplex sides. Color of each line corresponds to the pattern color. An object color is mapped with an associated pattern (the nearest pattern or pattern determined by an expert.

We use dashed 2-simplexes to illustrate the accuracy of the pattern recognition on the Fig. 4.

The edges of 3-simplex, shown in Fig. 5, are associated with four patterns. We demonstrate in Fig. 5 the objects of four patterns (A, B, C, D) and the investigated object related to pattern A within 3-simplex. Objects related to pattern A are red, to pattern B are yellow, to pattern C are brown, and to pattern D are green.

The results of each of the diagnostic, predictive decisions are shown in the form of points in 2-simplexes disposed on cross sections of 2-simplex prism.

Distance from the basis of the prism to i-th 2-simplex h_i' corresponds to the fixation moment of object under investigation features, and it is calculated based on the following formula:

$$h_i' = H' \cdot \frac{T_i - T_{\min}}{T_{\max} - T_{\min}},$$

where H' – length of 2-simplex prism preassigned by a user and corresponded to the investigation duration

T_i – timestamp of features fixation of object under investigation for i-th examination

$T_{\min}$ – timestamp of features fixation of object under investigation for the first examination

$T_{\max}$ – timestamp of features fixation of object under investigation for the last examination.

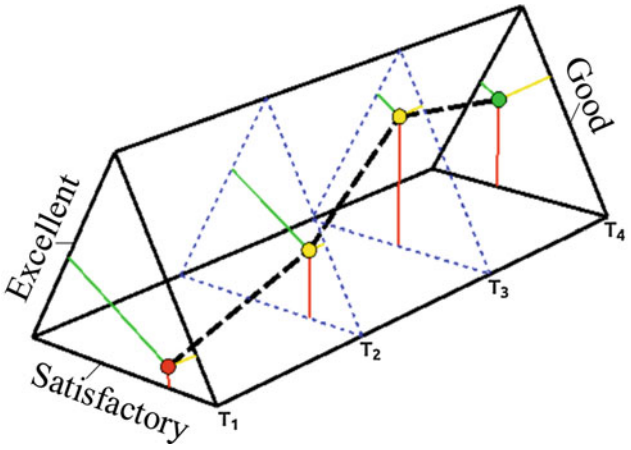
Since 2-simplex prism construction is based on 2-simplex, then the description of all 2-simplex objects is also correct for 2-simplex prism.

For intelligent geoinformation systems (GIS), the height corresponds to the distance from initial point to final destination. In this case the distance between two adjacent 2-simpleces corresponds to the distance between two points on a map.

Learning trajectory construction via 2-simplex prism is given in Fig. 6.

The edges of the 2-simplexes correspond to assessments satisfactory (red), good (yellow), and excellent (green).

We demonstrate learning path in the 2-simplex prism in Fig. 6. Height $\boldsymbol{H'}$ corresponds to time interval of learning, T_i ($i \in \{1, 2, 3, 4\}$).



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 6 Learning trajectory construction via 2-simplex prism cognitive tool

Software implementation of these models for intelligent system (IS) includes development of corresponded mathematical apparatus for transformation feature space to pattern space.

Using 2-Simplex Prism and 3-Simplex for Dynamic Diagnostic, Forecasting Processes and Dynamic Geoinformation Systems

Application in Learning-Testing Systems

Until 2015, we used 2-simplex and 3-simplex to make and justify decisions for dynamic processes visualization, modeling, and prediction (Yankovskaya 1997, 2011; Yankovskaya et al. 2003, 2015b; Yankovskaya and Semenov 2012). In 2015 we started to use 2-simplex prism for these purposes in various problem areas.

This section describes visualization of testing knowledge result in learning-testing system with estimation coefficients usage (Yankovskaya et al. 2016a, b, 2017a, 2018). In learning-testing system developed by us, respondent, after studying selected discipline, should pass MDT. During solution of this test, respondent actions map (RAM) is forming, which determines how well the respondent cope with different tasks based on the following abilities (skills):

1. Storage and reproduction of the material in unmodified form.
2. The reproduction of the material in modified form.
3. Extraction of new knowledge based on the studied material.
4. Problem-solving, etc.

It should be noticed that the different set of these parameters (a_1, a_2, a_3) can be transformed in same distances h_1, h_2, h_3 in case when sums of a_i for different sets are equal. So for that and similar cases, it is necessary to introduce the new parameter: a color saturation of point corresponded to the sum of a_i : $a_1 + a_2 + a_3$.

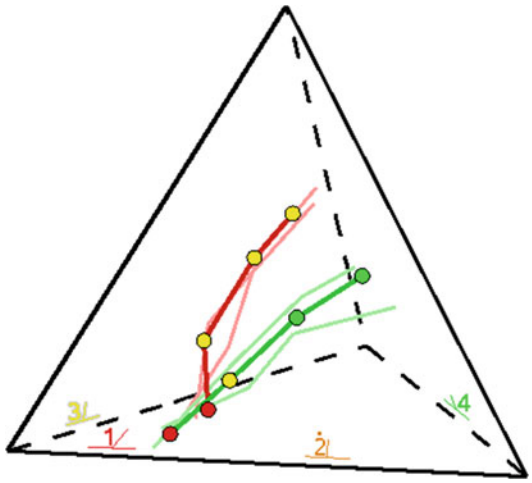
Example of 2-simplex prism usage for learning-testing systems is given in Fig. 6.

2-Simplex prism allows to represent dynamics for ability development of a respondent or a group of respondents. But it should be noticed that representation of test results of a big group of respondents with the usage of 2-simplex prism can be too complex and inconvenient.

Prediction of Students' Learning Results and Cognitive Graphics Tools for Its Visualization

We represent 3-simplex that visualizes dynamical process of learning and subdivides the respondents into two subgroups with close levels of learning abilities in Fig. 7.

One of the main research tasks is a fast creation of a simple prediction model prototype for a learning process. It allows to solve the following problems: (1) remove obstacles for solving other tasks



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 7 3-Simplex for dynamic processes cognitive visualization

of the current research; (2) get an estimation of an influence of learning process trajectory and its prediction visualization given for students on the speed of their learning; and (3) integrate a visualization library in the Web-based learning platform (Moodle). As a result, the main attention is focused on inputs and outputs of this model.

The prediction model has the following inputs: (1) a history of previous student testing results, which are obtained by MDT, described before, and (2) a time stamp of prediction. The output of the model is a predicted result which student should get at testing in preassigned time stamp.

Learning intelligent system (Yankovskaya et al. 2017b) is a good example of intelligent dynamic system. Control and prediction of students' learning results are the ones of the "hottest" problems in modern learning process. The respondents assess their results within a particular course module and explore the prospects for further intellectual development based on assignment performance and test results at each stage of learning cycle. The system implements the learning result prediction and suggests to students the next development directions: (1) research, (2) practical, (3) teaching, and (4) management activities.

We use 2-simplex prism to visualize and justify students' learning trajectories. The sides of prism correspond to the theoretical knowledge evaluation, skills to solve problems, and laboratory performance skills. A point in the space of these components at a particular time instant corresponds to the current evaluation of the above components combinations. In the process of learning, the point position can vary depending on the students' values correction. Preferably, this position should be within the tolerance area.

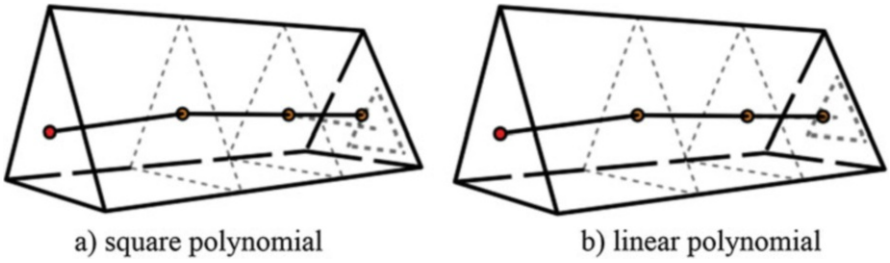
The prediction model has the following inputs: (1) a history of previous student testing results, which are obtained by MDT, described before, and (2) a timestamp of prediction. The output of the prediction model is a predicted result which student should get at testing in preassigned timestamp.

In the current research for a prediction, a simple extrapolation polynomial function is used. Polynomial degree p is configurable and can be used for its influence estimation on a prediction quality. For a polynomial function, the last $p + 1$ results of already performed tests by a student for each axis are used. A system of linear equations is constructed based on them and is solved via Gauss method. Confidence region prediction is calculated as delta between predicted and real result for the last performed test.

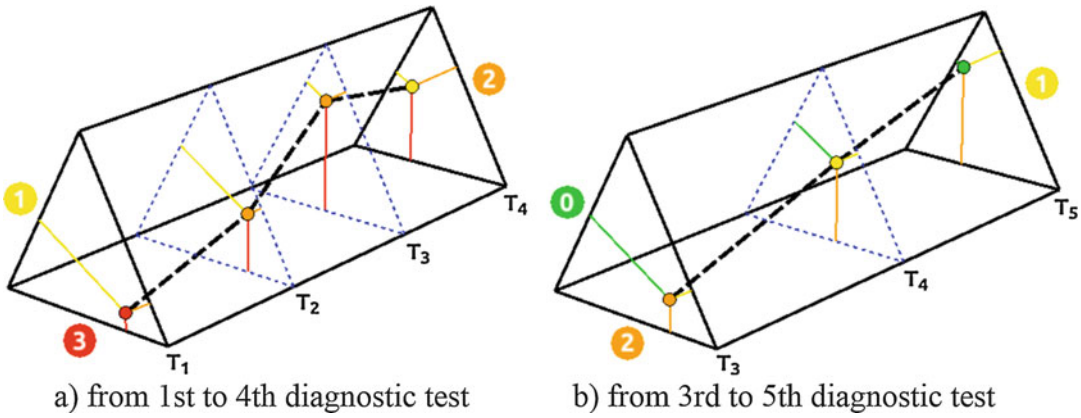
An example of student learning trajectory visualization and different prediction models is given in Fig. 8. By varying different models in the prediction process, it was found that for the majority of the respondents, the best prediction is achieved by using a linear polynomial model (the polynomial of the first power). In most cases this simple prediction model shows better quality of prediction than any other investigated model (using quadratic polynomial).

Decision Support for Diagnostics and Correction of Psychosomatic Disorders with Usage of 2-Simplex Prism

Diagnosis and intervention of organization stress with the usage of 2-simplex prism is another interesting example of CGT usage (Yankovskaya and Yamshanov 2016). The idea of diagnosis is based on a three-step diagnostics for each stage of organization stress (1, intenseness; 2, adaptation; 3, exhaustion) on the base of G. Selye conception. This scenario is interesting because there are four



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 8 Influence of the polynomial degree on the prediction quality



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 9 Results of diagnostic tests for organizational stress revealing using 2-simplex prism

patterns used (0 – for absence of organization stress) which is more that can be visualized and justified in 2-simplex prism. So two 2-simplex prisms can be used: one for the beginning of intervention (Fig. 9a) and another one for the ending of intervention (Fig. 9b).

The first test (T_1) reveals a level between the stage of exhaustion and the resistance stage and prepotency of the stage of exhaustion over the resistance stage. The second test (T_2) reveals that illness is decreasing from the exhausted stage (pattern 3) to the resistance stage (pattern 2). The third test (T_3) reveals that illness is decreased to a level between the resistance stage (pattern 2) and alarm stage (pattern 1). The fourth test (T_4) reveals prepotency of the alarm stage (pattern 1).

The second 2-simplex prism (Fig. 5) represents the transformation process from the resistance stage (pattern 2) to the absence of stress (pattern 0).

The fifth test (T_5) reveals the absence of the stress organization.

It should be noticed that the cognitive property of color is used in 2-simplex prism to represent dangerous diagnoses and patterns.

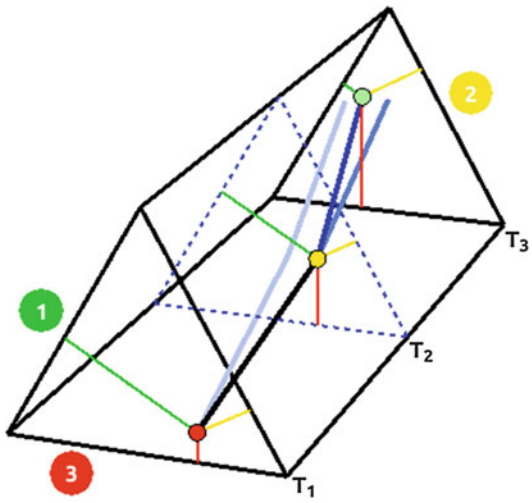
Cognitive Modeling

The cognitive modeling of a decision-making in the intelligent systems is one of the most important directions for creating intelligent systems (IS) in some priority areas of science researches and developing as medicine, psychology, sociology, environmental protection, energetics, systems of transport and telecommunication, control systems, etc. Manipulating some parameters of an object under investigation and using cognitive

tools of decision-making and its justifications in IS, we can perform a cognitive modeling based on the different kinds of knowledge representations.

An example of the modeling result on the base of prediction and therapeutic intervention with the use of 2-simplex prism (Yankovskaya and Yamshanov 2016) is presented in Fig. 10. After the first patient examination (T_1), the diagnosis is revealed – stage 3 (exhausted) of organization stress – and strategy of recovering is changed. With usage of mathematical model of a patient recovery process, it is possible to predict progress of patient recovery, which is shown in Fig. 10 as polyline of a light-blue color.

After the second examination (T_2), a progress of psychology stress recovering is diagnosed – organization stress is moved from stage 3 to stage 2 (resistance), but a real progress is worse than the predicted one. At this moment the doctor has two different strategies for continuation of recovering: purple and blue. The doctor uses this cognitive representation of different recovering strategies. He can choose one which gives the best result in the future. At this moment a strategy associated with a polyline of a purple color is more reasonable, because this strategy is applied to a patient. The model predicts full patient recovery until the moment of the next examination (T_3).



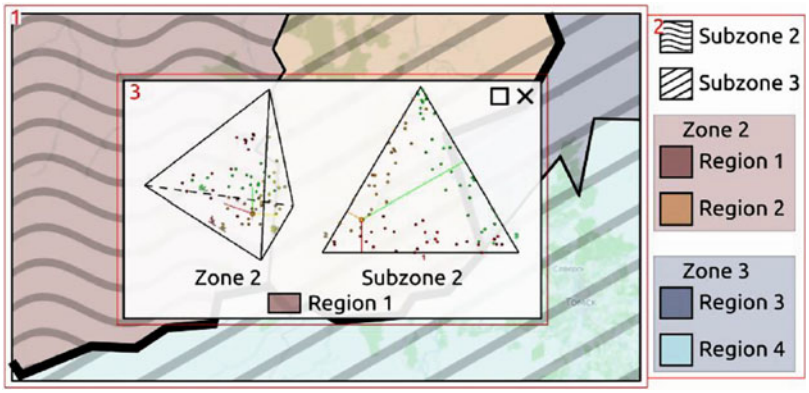
2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 10 Visualizing of a modeling result in 2-simplex prism

The cognitive modeling of decision-making is based on mathematical and computer methods with applying n-simplex family that allows optimizing a choice of influence of investigated object in accordance with a dynamical model of parameter change.

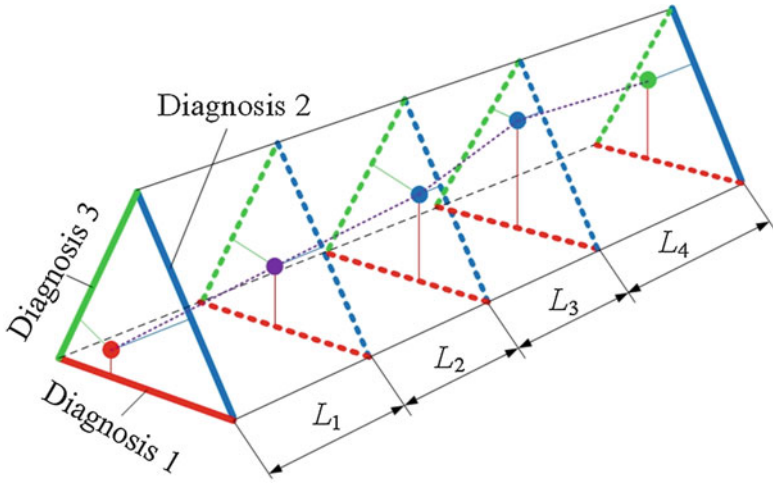
Using 2-Simplex Prism, 2-Simplex, and 3-Simplex for Geoinformation Systems

GIS (Ryumkin and Yankovskaya 2003) are widely applied practically in all spheres of human activity.

There are different scenarios for CGT usage in GIS. First common scenario is combination of ordinary reality objects (naturalistic CGT) and CGT, for example, map with real object and CGT overlay. Intelligent system of road-climatic zoning of territories (Yankovskaya and Sukhorukov 2017; Yankovskaya and Yamshanov 2014) is good example for this scenario. The free-distributed open-street maps with information layer overlay for the presentation of common information are used. Information layer presents road regions with borders and some information about its. This information is a number of zone and subzone which are determined for road region. A CGT for GIS visualization is presented in Fig. 11. Note that for the mapping of decision-making results with the usage of CGT, we use 3-simplex for the zone representation and 2-simplex for subzone representation in case when the number of subzones equals 3. The information layer is denoted by number 1. It is a transparent layer over the map. The thin black lines separate the different road regions. The different color tones are used for labeling the different zones (red color tone is used for zone 2; blue color tone is used for zone 3). Each color of the road region in every zone is unique color gradation from zone base color given from color transformation in the hue-saturation-bright palette (HSB palette). The wide black lines are used to separate the different zones. Hatching over road region shows subzone type. Only three hatching types are used and only two types from them presented in Fig. 11.



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 11 Visualization tool for representation of the map with zoning results



2-Simplex Prism as a Cognitive Graphics Tool for Decision-Making, Fig. 12 Results of diagnostic tests for intelligent geoinformation systems. L_1, L_2, L_3, L_4 – distances between geographical points

Another interesting scenario of usage is the investigation of dependency of some object parameters on the base of distance from some point. It is also reasonable to use 2-simplex prism for decision-making and its justification in intelligent geoinformation systems (Yankovskaya 2017). An example of health problem diagnosis on the base of distance is given in Fig. 12.

Conclusions and Discussion

Cognitive graphics tool (CGT) is one of the directions of artificial intelligence which is reasonable to use for any problem solution. CGT described in the paper are efficient for decision-making and its justification for pattern recognition problem in big number of software systems.

The most important advantage for the information visualization in 2-simplex prism is the opportunity to analyze in dynamics the object under investigation. It allows users to make decisions, justify them, and analyze changes of object parameters.

The new approach to the prediction of students' learning results based on MDT and 2-simplex prism is examined. Simple prototype of the prediction model for a learning process is given. Specificity of confidence region visualization for CGT 2-simplex and 2-simplex prism are described. The mixed DT (MDT) tools were verified on third year students' test results of speciality "Electrical Power Engineering." Variation of prediction polinome degree shows that for the majority of students the prediction results obtained using linear polynome is better than that obtained using square polynome. On this

basis the following hypothesis can be formulated: the second derivative is not constant for a learning process and cannot be used for correct prediction.

A lot of intelligent systems constructed on the base of intelligent instrumental system IMSLOG (IIS IMSLOG) shows that CGT usage is very reasonable for big number of problem and interdisciplinary areas.

The research was conducted in such universities as Tomsk State University of Architecture and Building, Tomsk State University of Control Systems and Radioelectronics, Tomsk State University, Tomsk Polytechnic University, and (Tomsk State Pedagogical University.)

Definition

3D Avatar is a representation of human users in a Virtual reality environment. It represents the body of the user, interaction of the user with the surrounding environment, and other users in the virtual world to enhance the realism of the overall experience. It facilitates collaboration among various users and the virtual environment in multiplayer games, remote collaboration meetings, virtual events, immersive learning classes, and many such applications.

Introduction

Remote collaboration and remote interaction with peers are rising steadily due to their apparent advantages of cost-saving, convenience, and scalability. Immersive technology such as virtual reality transforms the remote collaboration experiences through its unique features such as presence and realistic interactions.

Virtual reality, typically called VR, is a simulation of a new environment with visuals and interactions created through computing devices. It can be achieved through specialized hardware such as a head-mounted device (HMD) and haptic controllers. Vision and spatial audio rendering by HMD and haptic feedback through controllers make the experiences feel real for users. Virtual reality replaces physical reality with computer-generated content. It achieves realism through information visualization, guiding the user, and making the environment interactive through mediums such as gestures, movements, and audio (Porter and Heppelmann 2017).

Immersion, presence, and interactivity are the characteristics of virtual reality which make it suitable for remote collaboration with other users in a simulated world. Immersion in a virtual environment is achieved by designing the surroundings and content around the user. Content formats such as 360-degree photos, videos, and computer-generated graphical environments make immersion possible and productive. Presence in a virtual environment for the user depends on the representation of the user and other users in the same virtual environment. 3D Avatars are one of the representation methods to create a feeling of presence for all the users. Interaction with the environment and other users is the most effective way to make the entire experience productive and enjoyable. Based on the capabilities of the VR HMD, the experiences could be noninteractive to highly interactive. One such feature is degree-of-freedom, allowing users to move in the virtual environment and change perspectives differently (Pangilinan et al. 2019).

Other immersive technologies such as Augmented Reality (AR) and Mixed Reality (MR) superimpose digital content on a user's view of the physical world. It is achieved through a handheld device such as a smartphone or specialized hardware such as Mixed Reality Glasses. AR or MR enhance the surrounding reality with digital content but do not alter the physical reality. The interactions in AR remain restricted mainly to the digital overlay on the surroundings; however, in VR, the interaction extends to the environment and other users. This difference creates a need to represent the users in a simulated VR environment, and 3D Avatars play a significant role in this interaction.

Virtual reality has several applications depending on the need for interactivity, immersion, and presence. Sectors such as gaming, education, manufacturing, healthcare, military, and real estate have seen a varied degree of adoption of VR for applications such as remote collaborations, live events, and immersive learning (Rao and Dawarwadikar 2020).

Many of these experiences are individual experiences where the simulation and interaction limit to only virtual environments. Examples of these experiences are simulation games, movie- viewing experiences, and immersive browsing applications. However, in several experiences, the interaction extends to other users who share the same virtual environment. Examples of these experiences are multiplayer games, social network applications, live virtual event applications, remote learning, and professional collaboration applications (Bredikhina et al. 2020).

Need for 3D Avatars in Virtual Reality

Avatar, in simple terms, is the representation of a player in a video game or artificially created virtual world. Technically, it could be as simple as a 2D shape or as complex as a realistic 3D model. An Avatar enhances the gaming experience by the player's ability to identify themselves with their avatar's visual and behavioral characteristics. This perception is significant in virtual reality applications where interaction with the environment and other users plays a crucial role (Wauck et al. 2018). Research shows the psychological significance of 3D Avatars in players treating their Avatar as an extended body in the virtual world. However, it depends on the experience

and the player's attitude toward the experience. Environmental and interactive feedback from other users also influences the immersive experience of users (Rosa et al. 2018).

3D Avatars can be created in multiple ways, such as 3D laser scanning, photogrammetry, and machine vision. With the help of 3D scanners or appropriate software tools, realistic 3D models can be created from as simple as a single photograph to as complex as a full-body scan (Berdic et al. 2017; Jo et al. 2017). There are broad categories of how Avatars are created and presented. There could be entirely imaginative Avatars that do not resemble the player. Cartoonish-looking Avatars can partially resemble a player. However, realistic Avatars could resemble the appearance of the player to a great degree (Čeliković et al. 2018). This broad range of realism of Avatar is used in various applications based on need. The players' perception of themselves enhances their ability to align themselves with their Avatar through customizations (Wauck et al. 2018). Realistic Avatars invoke the illusion of virtual body ownership characterized by acceptance control and change in behavior of the player in the virtual world. The uncanny valley (i.e., the relationship between Avatar and the emotional response) is characterized by humanness, eeriness, and attractiveness. The realistic Avatars help in realizing self-presence as well as the copresence of other players. Avatars help build rapport between players sharing the same virtual environment (Latoschik et al. 2017).

The systems to create configurable and customizable Avatars are technically complex and require a certain level of expertise for users to create them (Čeliković et al. 2018). The creation of an Avatar requires a lot of time and effort on the artistic and technical sides. The effort is assessed based on the need of the application. Research shows that there is little to no effect on player's performance in a virtual environment and player's subjective experience, based on the quality of their Avatar in the experience (Wauck et al. 2018).

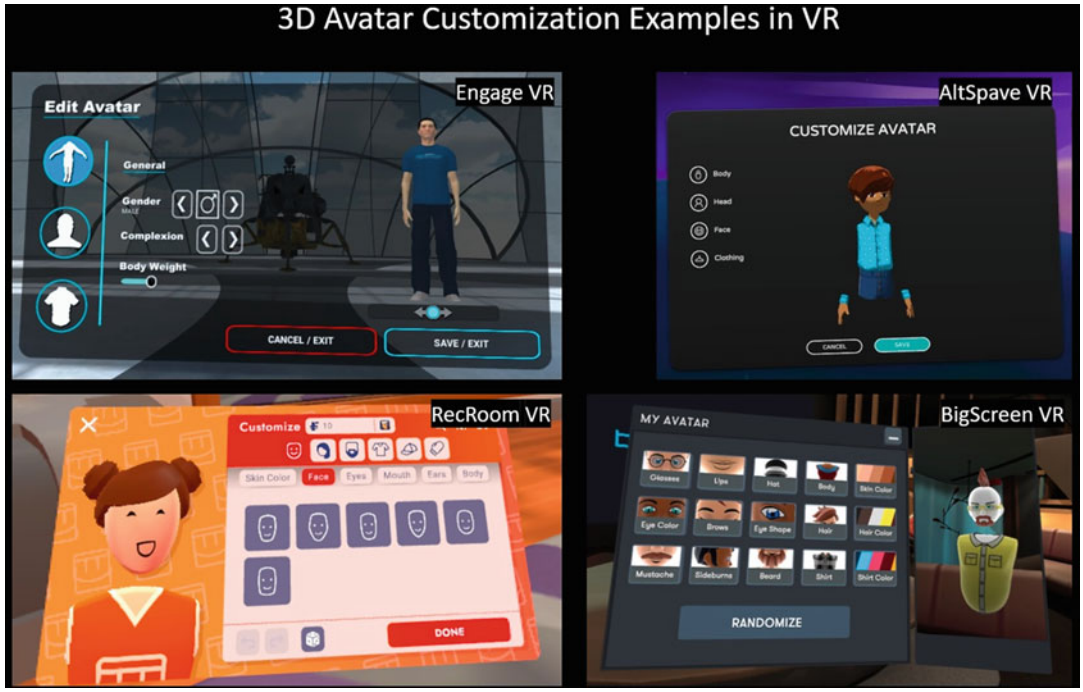
Virtual reality entertainment applications such as BigScreen allow multiple people to watch a movie in the virtual cinema hall. The interaction among the viewers happens through their Avatar movement, especially their head (tilting, nodding), body (changing places), and hands (waving, clapping). Oculus Venues or Oculus TV provides similar experiences to view an immersive stage performance while interacting with others. PokerStars VR and Racket Fury allow players to play Poker and Table tennis, respectively, with other online players. The interaction stays effective due to the use of synthetic Avatars. Social VR gatherings and events are available in AltspaceVR, VRChat, and RecRoom, where social groups can organize training, seminars, discussions, and many more such activities (Liu 2020).

What Makes an Avatar More Effective?

Presence – Avatar invokes body ownership among users, and research shows that presence is felt more effectively when players use a cartoon-like virtual Avatar that mimics players' outfits. Other possible ways to mimic player behavior are realistic Avatar created from photogrammetry of players and cartoon-like Avatars sketched by the artists (Jo et al. 2017).

Familiarity – Avatars feel most realistic to players when they are created with appropriate shapes and sizes mimicking the reality. Virtual body parts such as hands play a crucial role in VR experiences, and the appropriate size of hands and other objects play a critical role in creating realism (Ogawa et al. 2018). In some VR applications, the entire body of the Avatar is customizable, whereas, in some cases, only a partial body is visible and customizable. Figure 1 shows examples of 3D Avatar customizations available in some VR applications. Table 1 summarizes the customization options available for physical appearances in popular VR applications.

Expressions – Mimicking players' facial expressions on their Avatar strengthens the feeling of presence and interaction as nonverbal communication plays a significant role in human communication. Latest developments in hardware sensors and technology are accelerating the enhancement of Avatars through facial expression mapping in real time (Suzuki et al. 2017). While mapping players with Avatar's enfacement (similarity of player's face with Avatar's face)



3D Avatars in Virtual Reality Experience, Fig. 1 Examples of 3D Avatar customization in VR applications

3D Avatars in Virtual Reality Experience, Table 1 Comparison of VR applications for 3D Avatar customizations

Name of VR application	Avatar physical appearance customizations available			
	Body	Head	Face	Clothing and accessories
AltSpace vr	Body shape, skin tone, and nail polish	Hair, hair dye, hat, hat accent, and jaw shape	Eyebrows, eyes, mouth, nose, facial hair, and eyewear	Top, top accent, jacket, jacket accent, and bottom
Spatial VR	Body type (gender), skin tone			Shirt color
Engage VR	Body type (gender), skin tone, and body weight	Hair	Eyes, nose, and mouth	Tops, bottoms, shoes, and glasses
Oculus Venues	Body, skin tone	Hair	Face shape, face markings, and face lines	Eyewear, headwear, bindi, ear piercing, and nose piercing
RecRoom	Skin color, body	Face, hair style, hair colors, beard style, and beard colors	Eyes, mouth, ears	Clothing, shoulder, necklaces, belts, hats, glasses, earrings, and hand gloves
BigScreen VR	Skin color, body	Hair, hair color, moustache, sideburns, beard, and brows	Lips, eye shape, and eye color	Glasses, shirt, shirt color, and hat

and lip sync while talking enhance the embodiment significantly. Real-time communication with Avatars through speech using the onboard microphone of VR hardware also enriches interactions among players (Gonzalez-Franco et al. 2020).

Control – Avatar's sense of ownership is significantly influenced by self-control, i.e., controlling Avatar's movements and actions through the player's body movements. The player's point of view in a virtual environment (first-person view vs. third-person view) determines the realism of the Avatar for players interacting in groups. These factors often take precedence over the appearance of the Avatar alone (Fribourg et al. 2020).

Applications of 3D Avatars in Virtual Reality Experiences

Multiplayer Games

Games have been the most popular category of virtual reality applications since the launch of commercial VR headsets. In multiplayer games, interaction with the environment and interaction with other players are two distinct parts. For interacting with the environment, the embodiment and presence of hands play a pivotal role. Avatars do not influence perception much. However, in multiplayer games interacting with other players involves using Avatars to create the feeling of presence.

In role-playing games (RPG) such as rescue games, puzzle-solving games, or combat games, the realism of other players' Avatars enhances the feeling of presence, and own Avatar influences the players' social reputation. Often players choose their ideal self over their actual self while choosing customizations in the Avatar such as appearance, skin tones, and clothing (Wauck et al. 2018). Most fitness games and esports simulations, such as virtual boxing games, do not require full-body Avatars of the players as they project the first-person view to the players. The only Avatar of the opponent is considered relevant in such cases.

Professional Remote Collaboration

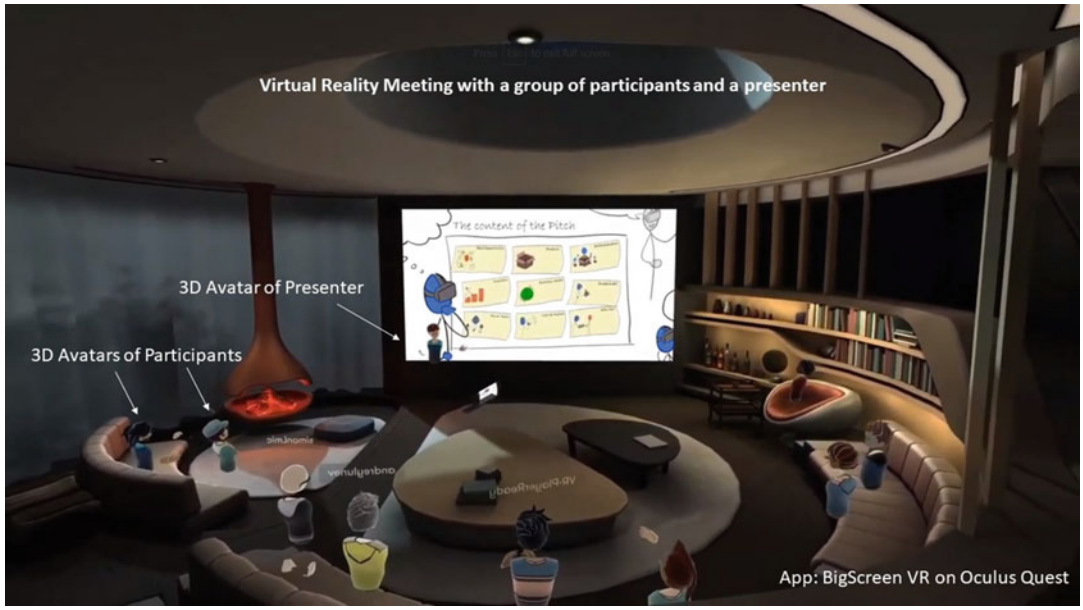
Remote collaboration at the professional level has increased over the last few years with various use cases. Utilitarian applications of virtual reality include remote maintenance support, virtual tours of factories, remote design/product reviews, and specialized applications such as remotely assisted surgeries. The feeling of presence expressed through 3D Avatars enhances the quality of the collaboration experiences, yet there are several areas of improvement. Generating realistic Avatars of multiple users, representing them in the virtual environment to identify them uniquely, and navigating the virtual environments without overlapping multiple Avatars at the same place are some of the challenges faced by current platforms such as VRChat, SpatialVR, and GlueVR (Liu 2020). Creating 3D Avatars professionally by scanning the user in 360 degrees surely enhances the usability and performance of professional collaboration applications (Kolkmeier et al. 2018) (Fig. 2).

Virtual Events

Virtual events are gaining popularity due to their cost and convenience benefits. Though VR hardware availability is the major hindrance in organizing large-scale virtual events such as conferences, stage shows, and live performances, the replacement of physical events into virtual events is on the rise. 3D Avatars and the feeling of presence in the virtual event venue provide an opportunity for participants to interact and network with fellow participants in events such as the entrepreneurship and innovation summit organized on the VirBELA VR platform (Jauhiainen 2021). The interactions among groups can range from attending a seminar or workshop to enjoying the after-event parties. Based on the situations, 3D Avatars and their realism play different roles in enhancing interactions. Additional factors such as virtual environment design and network speed for live experiences play a more significant role in overall user experience in such social events (Kreskowski et al. 2020).

Immersive Learning

Remote immersive learning has gained traction in the last few years, fueled by the availability of standalone VR hardware such as Google Cardboard and Oculus Quest. VR solutions and apps



Virtual Reality Meeting with a group of participants and a presenter
3D Avatar of Presenter

intercepted learnings at various levels, such as professional, personal, and academic, and various age groups such as schools, colleges, and corporate training. Professional skills such as technical skills and design skills can be taught in an immersive virtual environment facilitated by virtual instructors and the presence of other classmates remotely. During such interactions, Avatars of participants play a pivotal role in engaging in the learning experience. Hand movement, head movement, and voice interactions make the group- learning experience engaging. Personal skills such as public speaking are possible on a virtual stage with a simulated audience created through 3D Avatars. Such virtual learning experiences enhance motivation as well as the understanding of the learners (Gomes de Siqueira et al. 2021).

Limitations of 3D Avatars

Though 3D Avatars are an excellent way of representing humans in the virtual world, and there is a varying degree of realism available today technologically, we are still far away from the realism that matches the cinematic quality of characters. The costs and effort involved in improving the realism and features of a 3D Avatar are disproportionate to the benefits at the consumer levels; hence, most VR applications still use synthetic or cartoonish Avatars, which are widely accepted in current applications. So far, creating a realistic Avatar from a user image is the most popular and cost-effective technique. The alternate to 3D Avatars is holographic projections, which can simulate the humans' appearance and their realistic size and expressions. Technology for holographic projections and superimposing real human wrappers to create realistic cinematic characters is developing rapidly and will be incorporated into virtual worlds soon (Balamurugan 2017).

Conclusion

3D Avatars play an essential role in virtual reality experiences while interacting with other users and occasionally with the environment. Though the

technology to create realistic 3D Avatars is not fully mature and cost-effective, some workarounds are widely adopted across VR solutions. Depending on the experience, full-size body Avatars or only specific body parts such as hands or heads are used in VR experiences. VR users' presence and immersive experience largely depend on their perception of themselves in virtual Avatar and their social reputation, influencing their customization choices. As more and more social experiences and new-age VR hardware penetration are increasing, the need to develop 3D Avatars is growing over the last few years. However, alternates such as virtual humans projected through holographic projections will replace most synthetic 3D Avatars in the long run.

Advances in other technologies such as artificial intelligence, networks (5G/6G), and processing hardware (GPUs) will fast track adoption of realistic Avatars in VR experiences.

3D Game Asset Generation of Historical Architecture Through Photogrammetry

Chaitanya Solanki and Deepak John Mathew
Indian Institute of Technology, Hyderabad, India

Synonyms

Asset creation; Cultural heritage; Digital preservation; Game assets; Image-based modeling

Definition

Photogrammetry is the method of generating accurate photorealistic 3D models through organized assortments of photographs. Typically, photogrammetry is associated with the making of maps from aerial photographs but when the same system of algorithms are applied to documenting a 3D object, it can be used to create photo accurate 3D models of any building, object, or landscape desired.

3D assets in game-building refer to the three-dimensional models that the game employs as objects; the assets can range from stones to mountains, bricks to monuments. They can include every 3D object that can go into a game.

Introduction

A large spectrum of domains like video game production, virtual reality simulations, and augmented reality applications make intensive use of 3D-generated assets. There are many graphics suites that already offer a large set of tools and functionalities to manage the creation of such content, although they are usually characterized by a steep learning curve.

In games, the use of photogrammetry can enable the developer to build 3D objects that can be developed to look close to the original. Game developers have already adopted the method of photogrammetry to develop game objects and this entry highlights its use to accurately recreate historical representations in-game.

Resources Required for Photogrammetry

As photogrammetry uses images as input data to generate these models, hardware to record images like a handheld camera or a phone camera is mandatory to the process. Other requirements to generate models from photos are the image stitching software like Trimble Inpho, Reality Capture, Pix4D, AliceVision Meshroom, Agisoft Photoscan, and more. A few of these software, for example, Reality Capture, can take photos as well as videos as input data. Recently, software like Trnio and Sony 3D Creator allows the user to scan and produce 3D models with a smartphone as well.

After the model is generated, modeling software like Blender can be used to refine it by editing out any extra unwanted meshes or by making up for incomplete data. Following that, mesh manipulation software like ZBrush can be used to reduce the mesh count of the 3D object so that it becomes functionally lighter while retaining its visual aesthetics and intricacies.

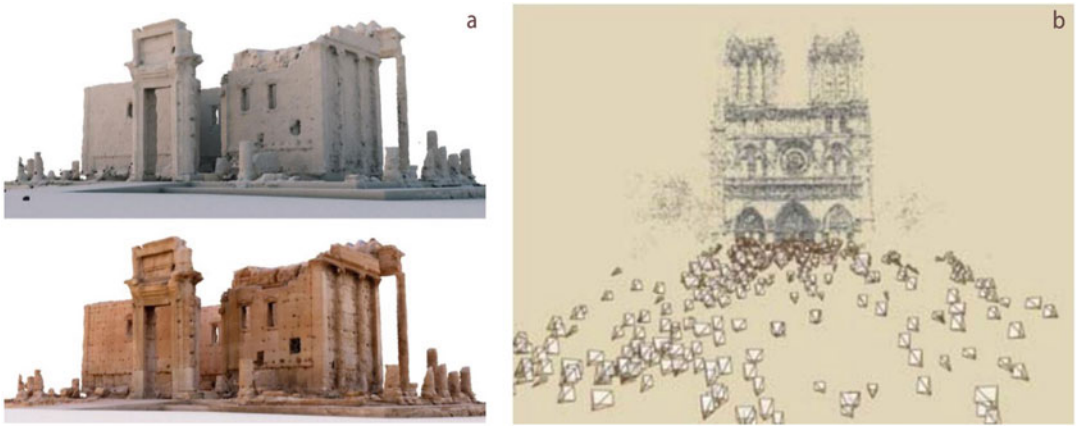
Digitizing Cultural Heritage Through Photogrammetry

In a study by Yilmaz and team (2007), the researchers reported on a two-story building that had burnt down twice and the conservation office of Turkey had needed to reconstruct the building through a restoration project. There happened to be no documentation available in the form of drawings or measurements as a reference to go ahead. Photogrammetry was then used to document the building holistically and re-photographed after the second fire to note the changes in the physicality of the structure. After processing the images in the photo-modeling software, architectural drawings could be obtained through the 3D model produced. With the help of the drawings, architects were able to estimate the three-dimensional measurements of the original building and with that, they were able to restore the building back to its original form (Yilmaz et al. 2007). This achievement of digitally countering architectural wear and tear can help games in employing photogrammetry to complete or re-create parts of worn down monuments into their original pristine condition for enhanced immersion.

Wahbeh et al. (2016) in their study go as far as to show that historical architecture, if well photographed even by tourists, can be recreated digitally using the available database online and some panoramic image-based documentation. Their research exploits the potential of multi-image reconstruction to model the destroyed temple of Bel, one of the heritage monuments of Syria (Wahbeh et al. 2016), see Fig. 1a. This is also in line with the image-based modeling system presented by Snavely et al. (2006) in their research, where they were able to interactively browse and explore large unstructured collections of photographs of a scene using a novel 3D interface. Their image-based modeling system could then produce a 3D model rendered solely from these collections of unstructured images, mainly retrieved from the Internet (Snavely et al. 2006), shown in Fig. 1b.

Using Cultural Heritage In-Game

A famous recent example of preserving a culturally important monument through digital documentation in a game is that of the burning of the Notre Dame cathedral in Paris. Built-in a gothic French architectural style, the construction was first started in the twelfth century and was not finished until 1345. In 2019, the cathedral became a victim of a fire breakout that damaged a significant part of its architecture. However, between 2010 and 2014, Ubisoft, a company that makes digital games, had intensively mapped the entire



3D Game Asset Generation of Historical Architecture Through Photogrammetry, Fig. 1 (**a**) Photogrammetric modeling of the "Bel" Temple in Syria. (Source: Wahbeh et al. 2016); (**b**) Photogrammetric modeling of a heritage building using large data sets of unorganized images. (Source: Snavely et al. 2006)

monument in an effort to recreate it in their game "Assassin's Creed Unity" (Elbaz et al. 2020). This indicated positively that historical monuments could play a huge role in level design in games.

This is in line with Statham's (2020) finding that models based on image-based modeling can be used in digital games as assets. The study also revealed how many of the major commercial games had also started employing photogrammetry at a large scale in an effort to render the game environment as close to real-life as possible (Statham 2020) (Fig. 2).

Conclusion and Discussion

The photogrammetric digitization of cultural heritage is a noninvasive method to preserve and archive historical monuments and sites. Although photogrammetry has been adopted by the gaming industry to provide for realistic landscapes and objects, it can also be used to authentically recreate historical sites and landscapes. Using this method also ensures that the intricacies of art objects are not lost due to their complexities as photogrammetry offers a more honest recreation when compared to 3D modeling. It has also shown to help experts recreate old monuments even when they have been the subject of partial wear and tear.

The methods of photogrammetry can also be applied to creating a true-to-reality environment around the monuments. The landscapes can be scanned thoroughly by imaging the surrounding objects like rocks, pillars, trees, etc., and they can then be rendered into photogrammetric models (Davis et al. 2017; Statham 2020). This can increase the authenticity of the digital recreation many folds and greatly help with level and environment design in-game as currently there is observed to be a lack of diverse environmental assets available that are representative of varying geographies.

It is also pertinent to observe and follow all the local and national laws that the structure falls under. In many countries, flying a camera mounted drone near a culturally important monument is not allowed. The process of

Photogrammetry; Terrestrial Photogrammetry

Definitions

Photogrammetry is a technique for estimating the exact position of surface points of an object by using multiple photographs. Aerial photogrammetry is based on the acquisition of photographs of a certain area from the sky, commonly by placing cameras on a plane, drone, or even a satellite, to create a topographical map or terrain model. Terrestrial photogrammetry aims at taking 3D measurements of an object, using photographs of that object taken from a camera positioned on the surface of the earth. Terrestrial photogrammetry is also referred to as close-range photogrammetry when the photographs of the object are taken at a close range.

Introduction

Photogrammetry is a manual process which requires in-depth understanding since it involves several aspects; for instance, the focal length and position of the camera when taking each photograph will impact the quality of the end result. However, recent technological advancements (increase of computational power, release of affordable, yet powerful, digital cameras, etc.),

along with the availability of free, user-friendly software, have simplified the process of photogrammetry. Combined with high-quality companion software, digital close-range photogrammetry is heavily used for the 3D digitization of cultural heritage.

The most widespread photogrammetry method for creating 3D models of real objects is based on structure-from-motion (SfM). SfM involves the provision of overlapping images of an object, captured from multiple viewpoints (see Fig. 1). Important data, such as the camera's position and orientation, are automatically calculated by specialized software, which also facilitates the 3D model creation and texturing process, extracting information directly from the set of overlapping images (Westoby et al. 2012).

3D Digitization of Cultural Heritage

The 3D digitization of cultural heritage is a common practice for the generation of 3D models used for exhibition, conservation, and protection, 3D printing-based replication, dissemination through web and mobile application channels, digital restoration of damaged parts, and monitoring of overtime alterations (e.g., when cultural assets are exposed to open environment) (Pieraccini et al. 2001). The 3D digitization process is tailored according to physical dimensions; thus, monuments and archaeological sites are digitized with the use of topographic techniques and aerial photogrammetry, whereas close-range photogrammetry is a better-suited, cost-effective 3D digitization solution for smaller-scale objects (Pavlidis et al. 2007).

Using Photogrammetry to 3D Digitize Cultural Heritage

Several studies document best practices and demonstrate the advantages of employing either close-range or aerial photogrammetry for the 3D digitization of cultural heritage. Some of these advantages are high accuracy of the produced 3D models and improvement of the safety factor during the digitization of hazardous or inaccessible areas (Remondino et al. 2005; Yilmaz et al. 2007; Fassi et al. 2013).

Santagati et al. (2013) provide an example of close-range photogrammetry in cultural heritage documentation, describing the 3D digitization process of a small chapel using Autodesk 123D Catch (recently rebranded to Recap https://www.autodesk.com/products/recap/), a widespread, cloud-based, free photogrammetry software (see Fig. 2a and b). The study revealed that close-range photogrammetry requires short

image processing times while offering high accuracy and quality even when nonprofessional cameras are used. Moreover, the metric accuracy for small objects (e.g., statures) is in the order of *mm*, while for medium to large objects and architectural buildings, it is in the order of *cm*.

On the other hand, aerial photogrammetry can be used to accurately digitize monuments (Grussenmeyer et al. 2008). An example is shown in Fig. 2c and d, where a castle's 3D model has been produced using photographs taken with a camera mounted on a drone, thereafter fed to a popular aerial photogrammetry software, Pix4Dmodel https://pix4d.com/product/pix4dmodel/.

Even if photogrammetry appears suitable for 3D cultural heritage digitization, it does not come without limitations. The most common ones are the long processing times to attain high accuracy (Fassi et al. 2013), the requirement of software products for structured photo datasets (Santagati et al. 2013), and the holes found on 3D objects when the physical object is not properly photographed (Remondino et al. 2005).

Conclusion

The 3D digitization of cultural heritage may be carried out through the manual creation of 3D models, by analyzing architectural plans, or via automated methods, such as laser scanning and photogrammetry. Even though there is an ongoing debate regarding comparative advantages of photogrammetry to laser scanning and vice versa, for 3D digitization in cultural heritage, complementary application of methods is considered as the most appropriate solution for digitization projects (Grussenmeyer et al. 2008).

Definitions

3D Printing is a form of manufacturing that adds materials together in layers to form an object. This is in direct contrast to subtraction manufacturing, which cuts away at a material to form an object. Primarily using plastics and/or metal, this form of manufacturing is rapidly developing and handling new, exotic materials. Its increasing adoption rate will have a big impact on the processes of distribution and production.

Introduction

Beginning in the 1980s, this technology has had an interesting development as it has reached its more mainstreamed status. The individuals that contributed to this interesting industry are varied across the globe. First being referenced as Rapid Prototyping, this industry donned the title "3D Printing" in the 1990s and has slowly become an almost ubiquitous household term today.

The History of 3D Printing

The 1980s is known for its retina-burning bright spandex pants, go-go dancers, and massively teased hair, but lesser known is the fact that it was the same decade that 3D printing was born. It flew under the radar of the public for several decades in almost complete obscurity as it

incubated. During that time they were more often to fall under the title of Rapid Prototyping (RP) technologies. Actually, 3D printing is interchangeable with quite a few terms. There is the previously mentioned Rapid Prototyping but there is also Rapid Manufacturing (RM), Additive Manufacturing (AM) technologies, Solid-Free Form technology (SFF), or Direct Digital Manufacturing (DDM).

What is so fundamentally different about 3D printing is that it uses an additive manufacturing approach, which is where precise amounts of materials are bound together in exact layers to form an object, versus the conventional subtractive manufacturing method, which removes materials to create products. Much like the varied titles that can be referenced to this form of manufacturing, so too are the hands that formed it. The history of 3D Printing is varied and expands the narratives of some very eclectic people.

Hideo Kodama of Nagoya Municipal Industrial Research Institute published the first working account of a photopolymer additive manufacturing system in 1981 (Tomioka and Okazaki 2014). Mr. Kodama's inspirational moment struck him over a year earlier while he was riding a bus home, reflecting on an exhibition in Nagoya where he was able to observe a machine capable of making letters utilizing liquid resin applied to a glass surface. The machine he witnessed at work was targeted towards the newspaper industry; however, upon reflection Kodama realized that he could harness this to create three-dimensional objects and began work on his concept (Tomioka and Okazaki 2014).

It was in early 1980 that he set off to work applying what he saw at the exhibition to a new way of creating items. After a viable system was brought to fruition, he began to show his peers his innovative concept while starting the process of filing a patent; however, without the interests or support of his peers, doubt soon overcame him and he quietly disregarded the effort. In a regrettable move, he did not complete a review period necessary for receiving the patent. Kodama is said to have created a two-story miniature house the size of a human palm by manipulating thin layers of resin; impressively, the 3D model held rooms, a spiral staircase, and even a dining room table (Tomioka and Okazaki 2014). Despite his tremendous personal success with the concept, Mr. Kodama felt disheartened and thought his concept was nothing more than a novelty, rather than the beginning of something revolutionary. Reflecting now, he says that: "I should have worked harder to make people understand the significance of my research results"(Tomioka and Okazaki 2014).

Other individuals, Alain Le Mèhautè, Olivier de Witte, and Jean Claude Andrè, filed a patent in 1984 on the Stereolithographic process but was abandoned by the French General Electric Company (now Alcatel-Alsthom) and CILAS, a subsidiary of the European Aeronautic Defense and Space Consortium for a "lack of business perspective" (Mendoza 2016). It seemed that this technology was doomed in its cradle as many overlooked its potential, while the inventors that produced the machines languished knowing something was brewing beneath the surface.

This is not to say that the people who contributed did not receive credit for some of the foundational research and thought processes that were fundamental to this industry. In 1995, Hideo Kodama was chosen to receive the Rank Prize, a privately funded British award for inventions, and was credited with creating the first of the key technologies for unlocking the rapid prototyping industry (Tomioka and Okazaki 2014). He shared this award with Charles Hull, our next inventor to highlight.

A few years after Kodama on the other side of the world we have Charles Hull, or Chuck, as he often goes by. This man is considered the father of 3D printing and is often where you hear the story of 3D printing begin. In the 1980s, he was working for an ultraviolet lamp company that added a layer of hard plastic onto surfaces, such as tables and countertops. After gaining permission from his superiors, Hull began to tinker after hours with a way to use the UV light to create tangible 3D objects from a Computer Aided Design (CAD) software, primarily utilizing the materials and science familiar to him through his daily work. He would experiment with photopolymers to lay the foundations of what would later cement him as the Father of 3D Printing. To which, there has been

contention to, and not just those hailing Hideo Kodama or the French as originators of the concept.

The material that Hull decided to use is called a Photopolymer. These materials are a type of plastic which harden and soften under different intensities of UV light. After a few design iterations, Hull created a finalized machine that manipulated minuscule plastic layers of photopolymer and each of these small layers combined to form the entire object. A simple cup, only a few inches tall, was the first item to be fabricated and represented a fundamentally different approach to our general notion of production (Davis 2014).

Through those long nights of toil, he invented the Stereolithographic (SL) process and filed for a patent in 1984, receiving it in 1986. He actually filed the patent 3 weeks after the French team and even further behind Kodama, but due to technical requirements and timing Charles Hull became the first person to patent and create a usable 3D printing method. What also lends to this standing as an industry founder is the creation of the Standard Tessellation Language (STL) file, which are still widely used today.

In the early 1990s, the Stereolithographic Apparatus, or SLA-1 machine, was created by 3D Systems with Charles Hull as one of the founders. Although with some error, this machine showed that complex parts could be built overnight or within a few hours using this method.

Primarily driven by tremendous cost, these cumbersome contraptions were more useful for transportation and other larger commercial industries. It was said that Charles Hull was obsessed with helping Detroit regain its competitive advantage as an influx of higher quality Japanese imports convoluted the market and moved manufacturing jobs away (Davis 2014).

Charles Hull was anticipatory of the gestation period that this type of technology would require while reaching full market awareness and publicity. In early interviews, he would project that it would take 20–30 years for the technology to find itself into more mainstream applications; however, it is with a combination of surprise and excitement that he now sees how this technology has grown in its capabilities (Davis 2014). His astute judgments, from projecting the amount of time the technology would require to become well-known to his imaginative nature that enabled him to contrive his invention, had helped to cement him as the father of this industry.

There were some, just like for Hideo Kodama, who felt that Charles Hull has been given too much credit for the creation of this industry while inadvertently leaving others in the dark; however, it takes a combination of belief in your product or process, dedication to create a company, and a little luck in the right market opportunity to make as large and noticeable of an impact as he has. As the saying goes: "to the victor go the spoils" – this is no less for Charles Hull. There are more people involved in the beginning of this industry than just he. So, we are going to wind back the hand of time a bit to capture our next inventor in the right light.

The 1970s was a time of expansion and exploration for many. For William (Bill) Masters, this was especially true. During this decade, he is said to have first speculated his form of 3D printing technology. From the South Caroline: A History of 3D Printing website, Bill Masters reflects on a kayaking trip he took where he recalls the moment when inspiration struck him:

> It was on a river trip. Back when I had the whole nine yards, the Volkswagen Van [and] the long hair, so when you're on the side of the river… and you're all laying there and looking up there at the sky at all those little dots up there – they call them stars. Why can't you make things in outer space? That's how it started; it started by looking at a star. (The Father of 3D Printing n.d.)

While he may have conceived his device early on, there were sets of personal circumstances that inhibited him from pursuing his musings of this concept until a few years down the road. Coincidently enough, when he did, he found it was around the same time that Charles Hull was also submitting his patent materials. That year was 1984, July 7th of 1984 to be exact. The date is special for William Masters as it was the date for which he filed the patent for his Ballistic Particle Manufacturing technology – patent #4665492 (USPTO Patent Full Text and Image Database n.d.-a). Most particularly, it is also a full

month ahead of Charles Hull's patent #4575330, which was filed on August 8, 1984 (USPTO Patent Full Text and Image Database n.d.-b). Charles Hull's patent application was accepted and published before the patent that Masters had submitted. To be realistic, it takes much more than a patent filing date and speculation of a concept to receive the credit of founding an entire industry.

Albeit, Masters contends that the birthplace of 3D printing is in North Carolina and also attributes the fact that Hull created a company along his patent almost immediately as a reason for his success. This is in contrast to Masters, who was not actively participatory until 1988 when he created Perception Systems, which later became Ballistic Particle Manufacturing (BPM) Technology. It was not until 1991 that his company, then newly titled as BPM Technology, obtained funding from Palmetto Seed Capital to create the machine based on his patent (The Father of 3D Printing n.d.). This was years after Charles Hull and other inventors had already forged a path ahead of him by creating different machines, processes, and were already selling machines based on their concepts.

In addition, it is distinct to note that even if the technology that Masters had created was to be as widely adopted as Hull's then there is doubt that it would have fared as well because it only creates structurally weak, hollow models. While Bill Masters may not have revolutionized 3D printing industry as a whole, he still filed a respectable amount of patents for technologies outside of 3D printing and also within this industry. Some of these patents include extruding fluent materials, 3D printing using pin arrays, and for the use of fluent material droplets (The Father of 3D Printing n.d.).

Selective Laser Sintering and Fused Deposition Modeling

As previously mentioned, there were many machines that also proliferated during this time as we come crashing into our next process. During the 1980s, there seems to have been an itch in many inventors' mind for machinery such as this, as our next innovator Carl Deckard comes into our crosshairs. Although many of these individuals were in completely different areas of the country, each seemed to be enraptured by automating the creation process behind three dimensional objects from the computer; however, just like their unique locations, each approached the concept in very different ways.

To say that Carl Deckard was young when he began his pursuit of this technology is an understatement. A freshman in Mechanical Engineering at the University of Texas in Austin, he spent his nights working in a metal shop that relied on the new, at the time, technology of Computer Aided Design (CAD) and began to daydream. He chose his major of Mechanical Engineering because he found that it was: "The closest thing to majoring in inventing" (Selective Laser Sintering and Birth of an Industry 2012).

Deckard was working for a facility in 1981 called TRW Mission, which crafted parts using CAD software; however, many parts were created from castings, or the castings themselves came from handcrafted casting patterns and he began to see that there was a potentially large market for creating casting patterns out of CAD Models. He envisioned lasers tracing themselves over fine layers of dust to bind together materials. By the time his senior year rolled around the only thing he needed to make his musings a reality were the parts to do so. An Associate Professor by the name of Dr. Joseph Beaman took the young student under his wing, then described as young and hungry, and the two began a trek to create this new form of machinery manufacturing.

Deckard began his transition into graduate school and, as luck would have it, the Mechanical Engineering Department was also moving to a new building, meaning that the budget had room for some equipment purchases. Beaman and Deckard took advantage of the opportunity and together they submitted a budget for the $30,000 worth of materials required to bring the idea to life. They affectionately dubbed the early stages of the Selective Laser Slithering (SLS) machine "Betsy," as it developed through the mid- to late-1980s. Although at first it was slightly crude method of production, as Deckard refilled a small box with powder by hand and ran the

computer which powered the scanner on top of the table. The first parts that were created were simply hunks of plastic to demonstrate that the concept could actually work. As he labored, though, more precise parts began to be produced by regulating the laser with the computer by writing code; upon evaluation, it was found that the parts produced were beginning to be of usable quality. At that point, Deckard called upon Beaman to write it up for his Master's degree because he had just created an entirely new and viable machine. He was none the wiser that this would lay the foundation of some incredible processes in 3D printing technologies in the decades to follow.

Deckard stayed at the University of Texas to continue refining the idea, receiving a grant from the National Science Foundation. They enclosed the rudimentary aspects of the machine into an electrical box, added a counter-rotating roller to level the powder between layers of the laser sintering (which was being done by hand before), and after the method had been fully polished the parts began to coming off the machine at a higher quality. It was then that the machine started to show the makings of something more versatile than just creating casting patterns.

Paul Forderhase, another graduate student, joined the efforts as the concept matured from being an undergraduate dream to a graduate project and was now gaining enough momentum to seek becoming a commercial company. An Austin business owner by the name of Harold Blair paired with an Assistant Dean of Engineering and occasional adjunct professor by the name of Dr. Paul F. McClure. They had become interested in the technology and the company was named Nova Automation – after Blair's existing company called Nova Graphics International Corporation. Deckard estimated that they would need $75,000 in startup capital to get off the ground, which was doubled by Beaman, and then doubled again by those overseeing the project bringing their estimated startup cost to $300,000 – this was just to keep the interests of Blair and McClure (Selective Laser Sintering and Birth of an Industry 2012).

After a few hit and miss opportunities for funding with several companies through the 1980's and 1990's, one of which actually involved William Masters from the then Perception Systems, Nova Automation received funding from the Goodrich Corporation. With this funding they were able to keep Blair on board and they renamed themselves the DTM Corporation. It was a reference to the term Desk Top Manufacturing or some have said it is a reference to the words "Deckard, Texas, and McClure".

Unfortunately, even after their hard efforts the technology was seen as a reflection of an industry still in its infancy and did not fare well. The majority shares were sold to a group of private investors, who then turned around and sold the company and concepts to 3D Systems, which allowed them to acquire key patent rights to the SLS technology. For 3D Systems to now hold the rights to SLS and SL technologies has played to the company's power position as the "world's leading provider of additive manufacturing technologies."

When it comes to market dominance, Stratasys is one of the few companies to challenge 3D Systems when it comes to their lion's share of control. Scott Crump, founder of Stratasys, patented the Fused Deposition Modelling (FDM) technology in 1989 (Perez 2013). Not only is it the most familiar form of 3D printing for the public, it was actually a pursuit with adorable roots. In 1988, Crump decided that it would be a wonderful idea for him to make a toy frog for his young daughter using a glue gun loaded with a mixture of polyethylene and candle wax (Perez 2013). With the support of his wife, and several burnt plastic pans later, he soon became obsessed and took his project to the garage – where he devoted many long weekends to it. He invested into digital-plotting equipment (which cost about $10 K) to help automate the process and the first prototypes of the toy began to be churned out.

His wife prodded and pushed for him to either turn this affixation of his into a viable company or give it up because he had already spent tens of thousands of dollars to produce one supposed toy for his daughter (Perez 2013). By that time though, it had evolved into a larger project, a mission, a higher calling than simply creating a plastic trinket toy for his beloved. He saw the

potential of a machine like this as he clacked away many nights in his garage.

The first of the Stratasys kits were $130,000 and not viable for the regular consumer market, nor really even for small businesses (Perez 2013). Much like 3D Systems, their efforts were revised and they began to focus selling his machines to larger corporations that had the funds necessary to fuel his refrigerator-sized machines. They liquidated all of their family assets and poured everything into their company to get it to that point. However, to even fulfill the first orders they would require the support of venture capitalist – they found a company willing to invest in the concept called Battery Ventures. The company took a 35% stake in the company for $1.2 million (Perez 2013).

Since then, Stratasys has evolved to be one of the largest companies in the world for 3D Printing – often battling for glory alongside 3D Systems. Scott Crump is a formal Mechanical Engineer who heads this company and he is credited with Charles Hull et al. as one of the founders of the 3D printing industry. In 2013, Stratasys strategically bought out MakerBot – who has become a household name for the home desktop 3D printer.

EOS and the Evolution of Selective Laser Sintering

This machinery was a global phenomenon during its development, Hans Langer formed Electro Optical Systems (EOS) GmbH in Germany around the same time that patent applications for the first forms of this technology began flying around the United States in 1989. Still true to this day, EOS machines are recognized for their superior quality of output that utilizes the Laser Sintering (LS) process. Their first 'Stereos' machines were sold in the 1990's, making them the first European provider of high-end rapid prototyping systems.

As to what motivated Langer to strike it off into unknown territory such as this was actually the cloudy doubt cast by others which enabled him to see the light of potential. At the time he was working for a company called General Scanning, which evaluated additive manufacturing technologies at a project level, and they decided not to invest into developing the technology. Langer remained unconvinced of their decision. He firmly believed that the technology would be the future. He formed his own company in 1989 and set off to create a new and viable industry. By the amount of sheer success that he has encountered, time has shown that his judgment was sound.

If the previously mentioned words "Laser Sintering" were familiar, you were keen. The technology was originally created in the United States and had an interesting pathway to this German-based company. When Carl Deckard's company failed and 3D Systems gained the U.S patents on the SLS technology, they also entered an agreement with EOS where 3D Systems would purchase a product line from EOS, which was directed at SL technologies, while EOS would be able to take over global patent rights on the SLS technology. This included other interesting developments of Laser Sintering, such as applications of metal manufacturing.

Under the same umbrella that Carl Deckard worked under, Suman Das also developed applications for SLS technology at the university, except he used metal powders for his Master's and Ph.D studies. It may come as a surprise to no one that he was also under the supervision of Joe Beaman. If that name sounds familiar it is because he was the same man who aided Carl Deckard in his pioneering in the original Laser Sintering concept. Under the Defense Advanced Research Project Agency (DARPA), Office of Naval Research (ONR), and Air Force Research Laboratory (AFRL) sponsorship, Suman designed and built two additive manufacturing machines and aided in co-inventing two laser-based additive manufacturing processes in metal for specific use in high performance aerospace components (Selective Laser Sintering, Birth of an Industry).Thus, enabling the ideas from a Texan student to reach the global market through a German company.

The development in technology in Germany can be dizzying due to massive amount of cross

collaboration between key companies. An offshoot process to SLS called Selective Laser Melting was initially developed in 1995 at the Fraunhofer Institute for Laser Technology (ILT), two Doctors by the names of Dr. Dieter Schwarze and Dr. Matthias Fockele, who then formed F&S Sterelithographietechnik GmbH.

Around the same time, a company by the name of TRUMPF Group began to work with their own brand of this technology based on the ILT research. What also makes them a powerful contender in the 3D printing market today is their extensive history of precision laser systems, and the fact that they also happen to hold exclusive rights to ILT DMLS patent portfolio. DMLS is Direct Metal Laser Sintering, which combines SLS and SLM properties. This technology was created in 2002 with a collaborative agreement between EOS and TRUMPF where they decided to share key technology with the goal of enabling more growth between the methods, based partially on the research that TRUMPF Group leveraged from the ILT.

Always eyeing advancement, in 2008 EOS/TRUMPF announced an agreement with a company called MCP (who was itself partnered with F&S Sterelithographietechnik) for patent licenses that expanded EOS and TRUMPF laser-sintering patents, specifically the machinery that enabled titanium and aluminum powder manipulation; however, the patents did not extend to North American and when MCP attempted to sell a machine, the Realizer, in the USA through 3D Systems they landed in some hot water with EOS. They had technically performed patent infringement and EOS pursued a lawsuit against them. After settling the lawsuit for an untold amount of money, MCP (now MTT) went through some hand changing and consolidation to reform itself as a private company under SLM Solutions GmbH, who now sells their own brand of SLM machinery.

Conclusion

3D printing is bounding forward quickly, crafting vehicles, organs, and even homes in its wake. The decades will blur by and the innovation will exceed our expectations, as they did for Charles Hull. 3D printing is set to carve an interesting niche for itself, uniquely performing where traditional methods fail, while also turning the table of development. While it may truly never replace mass manufacturing, the changes it makes in our supply chain and the way we view manufacturing as a whole can cause us to change as creators and consumers. This is where the power of 3D printing lays, in its ability to enable creativity and innovation in places we thought it was stagnate, to bring increased individuality to the products we consume, and rethink our manufacturing process now that we are brought more intimately to it.

3D Puzzle Games in Extended Reality Environments

Prasad S. Onkar and Devi Meghana
Department of Design, Indian Institute of Technology Hyderabad, Hyderabad, India

Synonyms

Augmented reality; Extended reality; Mixed reality; Spatial interactions; Virtual environments; Virtual reality

Definitions

Augmented reality (AR): It can be defined as a medium where the virtual models are augmented onto a real-time objects, or a virtual information overlayed on top of a real-world objects or space.

Virtual reality (VR): It can be stated as a medium which provides three-dimensional immersive environments which allow the user to interact with the digitally created objects.

Mixed reality (MR): As the name suggests, it is the medium where virtual, i.e., digital objects and real-time physical objects coexist and interact with each other.

Extended reality (XR): It is an umbrella term which encompasses technologies like VR, AR, MR, etc. and their combined experiences.

Introduction

Games bring the attention and indulges a person in an activity irrespective of the age. Games have been around humans since the dawn of history and they are inextricably intertwined with the human evolution. In recent times, as the digital technologies evolved, video games became more popular among all age groups of people. In that, puzzle video games were primarily designed to keep the player/s engaged by testing the ingenuity or knowledge. The games were designed with increasing levels of complexities to cater to the tendency of the players to move to higher complexities and challenges. Thus, once the player solves or reaches the end of a level, it gave the sense of satisfaction which in turn enhanced the engagement of the player with the games. Dissected or jigsaw puzzles are spatial rearrangement games which involves visuospatial thinking and problem-solving. John Spilsbury, a London-based cartographer, is considered as the creator of jigsaw puzzles (Williams 2004). In 1760s, he first created such a puzzle by pasting the map of different kingdoms in Europe on a wooden plank and dissected it into the maps of individual kingdoms. Such maps were marketed as tools for geography education for children. These puzzles are challenging and also enhances the motor ability and constructional praxis in children. These games have come off the age through different transformation. The early transformations include "three-dimensional jigsaw puzzles" which was patented by Hammer Willie in 1961. Host of interesting geometric puzzle designs have been explored by Stewart Coffin (2006). Many researchers have explored algorithmic analysis and synthesis of such puzzles (Song et al. 2012). Though the computers can create interesting puzzles in the digital environment, they are unable to actively engage with the players, unless the interaction medium supports this complex perceptual task. Toward this, a host of digital interactive technologies have been developed to make seamless interaction with the virtual digital world. The advent of technologies like virtual reality (VR), augmented reality (AR), and mixed reality (MR) have shown a great promise to facilitate such puzzle games in

the modern era. Such interactive gaming modalities have the potential to solve the present-day challenges. This article presents the role and possibilities of 3D puzzle games in the context of spatial, immersive interactive technologies like VR, AR, MR, etc. which are collectively known as extended reality (XR) technologies.

VR in Gaming with Puzzles

Virtual reality (VR) immerses the human's mind into another realm, thus by deceiving the human senses, which aligns the brain with alternative reality. In VR, stereoscopic displays, software platform, motion-tracking hardware, etc. are used to generate a virtual environment. In VR systems, the user is unaware of the physical (real) surrounding. This also implies that there is a higher degree of engagement with the virtual environment and enhanced cognitive involvement. Perception of spatial arrangement is essential for virtual games with puzzle metaphor. Such games developed for applications like spatial perception (Rasheed et al. 2015) and anatomy education (Pohlandt et al. 2019). To facilitate greater immersion into the virtual environment, the mapping between the human sensorial inputs corresponding with the spatial transformation of virtual objects in the scene should be consistent. Thus, it is the responsibility of the VR content developers to achieve realistic immersion into the virtual environment.

AR/MR in Gaming Puzzles

AR technology can help in transforming a physical space through spatial interaction with the virtual data overlapped to create an engaging environment. In the context of assembling a 3D puzzle, user gets continuous feedback based on their actions while assembling the puzzle pieces. One such example is demonstrated in using projection-based technique (Kitagawa and Yamamoto 2011), in which the user is guided by projected image on the tabletop. These technologies facilitate physical puzzle interactions with digital overlay of information to support the game play. Augmented reality system integrates computer-generated information with the help of sensors to create 3D virtual models, which has to be calculated along with the user's position and orientation. These technologies are also ubiquitous because it can be deployed on the smartphones, and utilize the functionalities of the AR applications (Roberto et al. 2019). This technology has potential to greatly transform interactive experiences of 3D puzzle games.

Interactions in XR Media for Puzzles

Physical puzzle games make the users to think logically by interacting with the pieces to solve the puzzle. A game's physical aspect consists of interactions such as touch and feel, and emphasizes on physical skills of a player in solving it with emotional cues. Computer games have limitation of physical interactions to the players' use of interface hardware to play the game (Nilsen et al. 2004). Puzzles require users to randomly arrange the elements, thus entailing the cognitive activities such as exploring all the possibilities and improving the strategy development. 3D puzzles help users to think differently than the traditional 2D puzzle pieces. As 3D puzzle would have an extra dimension to it and becomes more challenging to solve it than a 2D puzzle set. Using 3D puzzles as a metaphor can greatly enhance the interactions in XR medium. The major potential of XR is in altering how we perceive the virtual world with the help of computer-mediated user experience. This disruptive behavior in leading to paradigm shift in the applications developed in various domains like health care, education, entertainment, military applications, etc. Thus, such user interfaces must have a richer visual content and seamless interaction between real and virtual worlds with the help of intuitive sensing, tracking, and feedback technologies. One of the important factors in facilitating interactions through XR media is to have reliable spatial interactions. The 3D puzzle metaphor is extremely

useful to achieve these seamless interactions as described in the framework presented in the following section.

Framework for Interactions in XR

Based on the prior experience of developing XR applications, a framework is derived which would be useful for developing applications for any routine task which can be made more engaging and convenient for the user with the help of XR technologies.

Assembling the components of a puzzle consists of various steps and should be done in a systematic sequence. Hence, it involves an architecture integrating software and hardware. The architecture of the system is shown in Fig. 1. Here, when the user gazes at a three-dimensional object through a hardware such as Microsoft HoloLens® which has camera embedded to it, the spatial information of the object is captured by the camera through the markers and this information is provided to the software to process and identify the object. Once the objects are detected, the corresponding animations will be triggered and information explaining the process of interactions of physical objects will be provided. Further actions are triggered depending on the user feedback, and this process will continue until the task is completed successfully or any other conditions of termination of the interaction. Robust implementation of this framework for creating a better user experience depends on the components of the framework described below.

Object Recognition

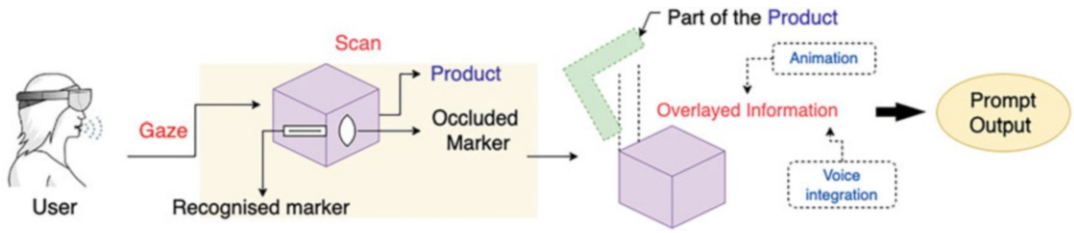
To augment any physical task with the support of XR technologies, it is required to capture the physical scenario into digital format. Thus, object recognition technologies will help in capturing the physical scenario. There are multiple aspects of identifying the object or object recognition such as the perspective views and the angles related to the object. Image-based object recognition technologies are useful for 2D planar scenario. In 3D, capturing and identification of objects is complex. Though there are many technologies like 3D scanning (Tucker et al. 2014), depth cameras (Langmann 2014) etc. to reconstruct a 3D space, but still the challenge is to solve it in real time.

Movement or Orientation

When a successful object recognition is done, the next aspect is to facilitate movement or the orientation of a particular 3D object. When the dynamic object moves in the space, one can understand the transformation components such as translation, rotation, scale, etc. covering all the three axes.

Interaction Between the Physical and the Virtual Objects

Interaction can be defined as communication and reciprocal actions between two entities to reach a common functional goal. The interaction between a physical object and the virtual object can be defined as both representations are interdependent. The interaction of bimanual motor skills enables the user to perform interactions that can be through narrative essentials such as hand gestures, voice, or gaze.



3D Puzzle Games in Extended Reality Environments, Fig. 1 *Framework* of interaction in XR system with voice interaction

Voice Interaction

Voice is an important aspect as it is a part of interaction by which one can quickly get responses from the system. The role of virtual voice assistant can be seen as an embodiment. As mentioned earlier about the continuous feedback, the role of voice is essential when the interactions are bimanual and also when the user has to perform multiple interactions.

Applications

Virtual reality can provide seamless immersive experience in interactive 3D medium. The essence of virtual gaming can be put into various fields such as education and training, which can be very engaging and enhance users' expertise (Rasheed et al. 2015).

Mixed reality has various entities such as specialized equipment and efficient software, and with the recent advancements in technology many devices have emerged as potential interfaces, such as Microsoft HoloLens®. Hence this technology has become ubiquitous and can be used in various sectors such as education (Rasheed et al. 2015), training and simulations (Mujber 2004), product repair and maintenance (Paravati 2017), entertainment, health, and military applications. Majority of MR's potential can be used in product assembly and the execution of industrial tasks. MR is also used in construction industry as a tool to BIM (building information modelling), to understand the three-dimensional models (DaValle and Azhar 2020).

3D puzzles are one of the best examples of an assembly. The user has to carefully place the pieces of the puzzle in such a way that it makes it as a single unit. Often, users fail to assemble the parts of a device or a piece of furniture. Thus, it results in failure of the product and have to end up losing money for repair. Solving 3D puzzles are highly engaging task as it plays with the third dimension as compared to a traditional 2D jigsaw puzzle. Such interfaces are extremely relevant to the applications like manual assembly of machine components. Puzzles can be interesting metaphors for VR system designs. Especially in VR games, puzzles help in developing mechanics of the games (Nyyssönen and Smed 2021). Thus, the use of technology such as XR can help in guiding the novice users to a precise point/dimension by detecting points on the physical objects. It helps in building a virtual space to visualize content and solve problems such as tedious job of assembly into an interesting one.

Interactive design; Interactive genetic algorithm; Interactive room layout

Definition

IEC is the interactive optimization system incorporating human tasks. 3D room layout system using IEC is the application of IEC, and it evolves layout according to the user preferences.

Introduction

Designers usually build renderings to create a new layout, and they reorganize it to fit a customer need. Furthermore, customers can understand shapes intuitively if they provide the 3D room layout. Numerical optimization approaches that optimize parameters constructing the 3D room layout can automate these works. However, it is difficult to create a model equation that emulates human thoughts because it is a subjective personal preference. Therefore, optimization systems incorporate the human tasks that evaluate the fitness of solutions manually. These systems usually use interactive evolutionary computation (IEC). This approach is similar to the process of improvement in animal and crop varieties. Some evolutionary computing algorithms implement IEC. The most famous algorithm is interactive genetic algorithm (IGA), and some studies use parallel distributed interactive genetic algorithm (PDIGA), interactive differential evolution (IDE), interactive particle swarm optimization, and interactive genetic programming (Takagi et al. 1998, 2009). This entry focuses on IEC and interactive 3D room layout, and it especially treats the system that uses IGA. The remainder of this entry organizes as follows. Section "Algorithms for IEC" gives the algorithms for IEC and examples of some applications. Section "Layout Generation" shows the studies that generate 3D layout interactively. Section "Quantitative Evaluation Techniques and Problems of the IEC-Based Systems" describes quantitative evaluation techniques and problems of the IEC-based system. Finally, section "Summary" summarizes this paper.

Algorithms for IEC

Richard Dawkins famed for *The Selfish Gene* began the study of IEC (Dawkins 1986). Afterward, various fields such as arts, engineering, education, and entertainments incorporate IEC (Bentley 1999). Takagi organized the applications of IEC between 1986 and 2000 (Takagi 2001). Table 1 lists the major application. The following are specific advantages of IEC:

1. Personalize applications based on user preferences.
2. Incorporate knowledge and heuristics of users to the system.
3. Aid creativity of users.
4. Provide user-friendly applications that need not special skills and knowledge.
5. Analyze user preferences by using optimized solution.

Interactive Genetic Algorithm

Genetic algorithm (GA) is a heuristic search algorithm, and it bases on the Darwinian theory of evolution. It finds the optimum solution by generating individuals that can be the optimum solution. Each individual that is in the population develops through the fitness function that determines the ability to solve problems, and crossover and mutation elevate individuals. IGA replaces the fitness function with the user evaluation to incorporate user preference and knowledge.

Table 2 shows the pseudo-code for typical IGA. The user rates the evolved individuals, and IGA generates new individuals according to the user evaluations. The following are specific procedures:

1. Initialization: This process generates the initial individuals. Typical IGA creates genes configuring an individual randomly.
2. Evaluation: This is the human task. The user rates individuals based on his/her subjective preference. IGA uses these evaluations as the fitness values to evolve the current individuals.
3. Selection: This process selects some highly rated individuals as parents to create a new generation. The following are specific selection methods:
   - Roulette selection: This method selects parent individuals according to a rate that is proportional to the fitness values. Typical roulette selection uses the selection boxes that have room according to the fitness values and random numbers, and it selects the individuals by checking the random numbers that are in the selection boxes. The following is the probability selecting ith individual, where n is the number of individuals and f is a fitness value.

$$p_i = \frac{f_i}{\sum_{k=1}^{n} f_k}$$

   - Tournament selection: This method selects parent individuals by using knockout competition.
   - Elitist selection: Roulette selection and tournament selection have the potential to lose the best individual because they are probabilistic methods. This method bequeaths the elite individual to the next generation, and it does not apply crossover and mutation to the elite individual.

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 1 Examples of IEC applications

Creativity	Comfortable design	Personalize
Biomorph	Lighting	Hearing aid
Face image	Web page	Vision aid
Screen saver	Vehicle	Image retrieval

Modeling	Interior layout	Knowledge acquisition
Animation	Clothing	Robot arm control
Music	Schedule	Educational aid
Voice	Game	Advertising
Artificial life	Story composition	Seasoning adjustment

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 2 Pseudo-code for typical IGA

```
IGA ( )
  generation = 0;
  create initial group of individuals;
  REPEAT
    fitness = USER (current group of individuals);
    IF user is satisfied THEN RETURN the best individual;
    i = 0;
    REPEAT
      select two individuals based on fitness;
      perform pcrossover;
      perform pmutation;
      insert two offspring into new group of individuals;
      i = i + 2;
    UNTIL i > predefined number of individuals;
    generation = generation + 1;
  UNTIL generation > predefined number of generations;
STOP
```

4. Crossover: This process transposes gene sequences of two individuals. The following are specific crossover methods:
   - Single-point crossover: This method splits a gene sequence into two halves. Children inherit the parent gene sequences half-and-half.
   - Multi-point crossover: This method has some split-off points. Children inherit the parent gene sequences alternately.
   - Uniform crossover: Children inherit the parent gene sequences according to a randomly generated mask.
5. Mutation: This is a way to change a part of gene in an individual randomly with a fixed probability. It is a useful way to prevent the initial convergence. Typical mutation uses the reciprocal of a gene length as the mutation rate.
   - If a specific individual generated in an early stage has an extremely high fitness value, IGA may select it as an optimal solution. This is the initial convergence, and it is a problem in IGA. It converges exploration in the early stage, and solutions lose the diversity.

IGA iterates these operations (2–5) until the user obtains a satisfied result or the number of iterations exceeds the predefined constant. The performance of IGA depends on the operators. There are many methods other than listed above (Koza 1992) (Fig. 1).

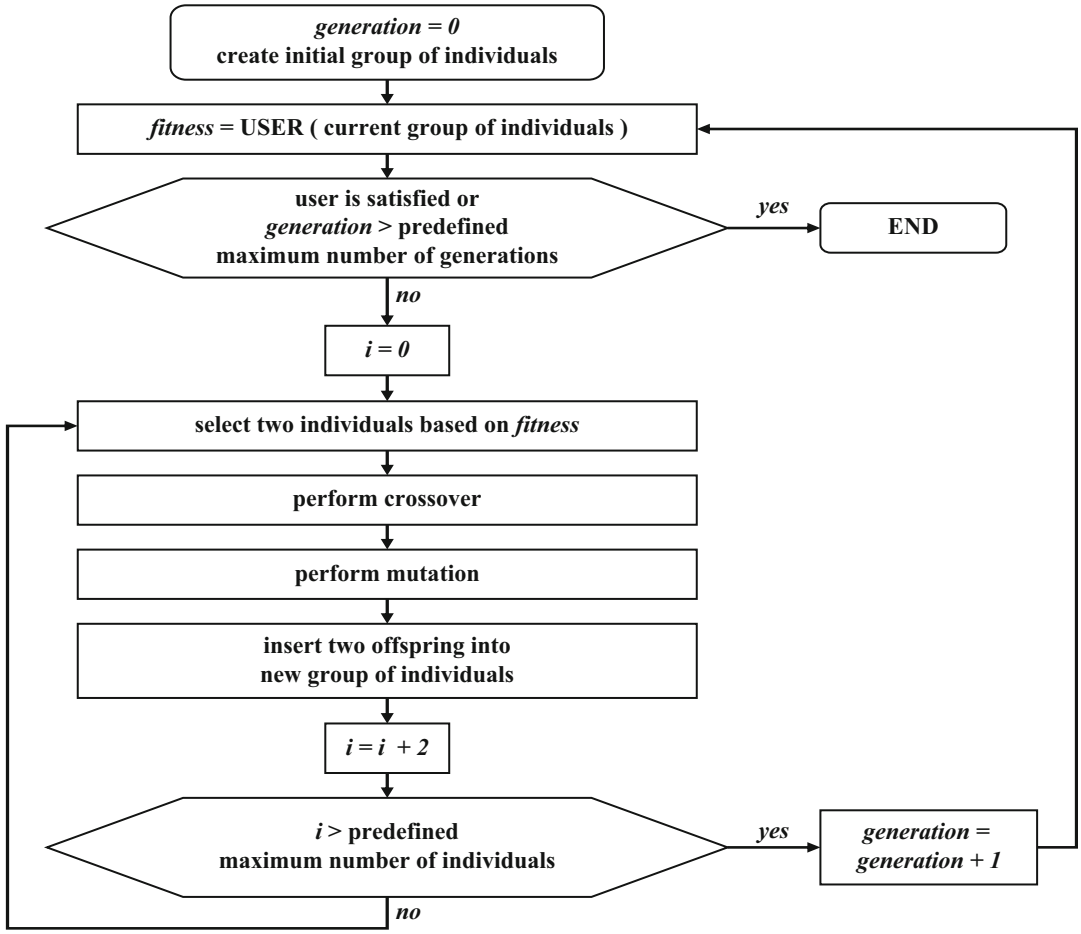
Gene Expressions IGA has many types of gene expressions as with GA (Back 1996). An individual has the genotype and phenotype. GA operators operate genotype, and the user evaluates phenotype. The following are typical genotype expressions:

(a) Binary code: This method expresses genes as binary codes.
(b) Gray code: This method expresses genes as the codes that maintain the difference of adjacent nodes at 1 bit, and it facilitates the local search. The following are the conversion equations of binary codes and gray codes, where k is the bit location and n is the most significant bit:

$$g_k = \begin{cases} b_n & (k = n) \\ b_{k+1} \oplus b_k & (otherwise) \end{cases}$$

$$b_k = \sum_{i=k}^{n} g_i (mod\ 2)$$

(c) String: This method expresses genes as strings. Mutation operator changes a gene element within the predefined character set.
(d) Real number: Real-coded GA uses real numbers directly. The IGA that emphasizes continuous values uses this coding. It can generate children around the parents. However, real-coded GA needs the special crossover operators such as unimodal normal distribution crossover (UNDX). It generates children according to the normal distribution obtained from three parents (Ono et al. 2000) (Table 3).



3D Room Layout System Using IEC (Interactive Evaluational Computation), Fig. 1 The flowchart of typical IGA

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 3 Typical genotype expressions

Phenotype	Binary code	Gray code	String	Real number
1.0	000	000	"1.0"	1.0
1.5	001	001	"1.5"	1.5
2.0	010	011	"2.0"	2.0
2.5	011	010	"2.5"	2.5
3.0	100	110	"3.0"	3.0

Parallel Distributed Interactive Genetic Algorithm

Miki et al. proposed parallel distributed interactive genetic algorithm (PDIGA) (Miki et al. 2003, 2006). Table 4 shows the pseudo-code for typical PDIGA. This algorithm extends IGA to parallel distributed model, optimizing solutions according to the multiuser preferences. It can generate the new solutions combined with other user evaluations, used in consensus building system. PDIGA inherits the performance of PDGA that can reduce the computation time and avoid the initial convergence of GA. PDGA connects each computer and

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 4 Pseudo-code for typical PDIGA

```
PDIGA ( )
    generation = 0;
    create initial group of individuals;
    REPEAT
        receive an elite individual;
        insert the elite individual into current group of individuals;
        fitness = USER (current group of individuals);
        send a new elite individual;
        IF user is satisfied THEN RETURN the best individual;
        i = 0;
        REPEAT
            select two individuals based on fitness;
            perform crossover;
            perform mutation;
            insert two offspring into new group of individuals;
            i = i + 2;
        UNTIL i > predefined number of individuals;
        generation = generation + 1;
    UNTIL generation > predefined number of generations;
STOP
```

runs IGA on those computers. PDIGA uses the migration that sends and receives the elite individual each user selected, incorporating other individuals.

They also proposed global asynchronous distributed interactive genetic algorithm (GADIGA). It compiles the elite individuals in a database so that each computer can migrate them without synchronism. Each computer gets the elite individual from the database, incorporating it in own group of individuals.

Interactive Differential Evolution

Storn et al. proposed differential evolution (DE) that is a population-based descent method for numerical optimization (Storn et al. 1997). The following are specific advantages:

1. Completeness: It searches comprehensive optimized solution.
2. Efficiency: It needs a small number of times of evaluation.

Takagi et al. explained advantages to use DE for IEC as follows (Takagi et al. 2009):

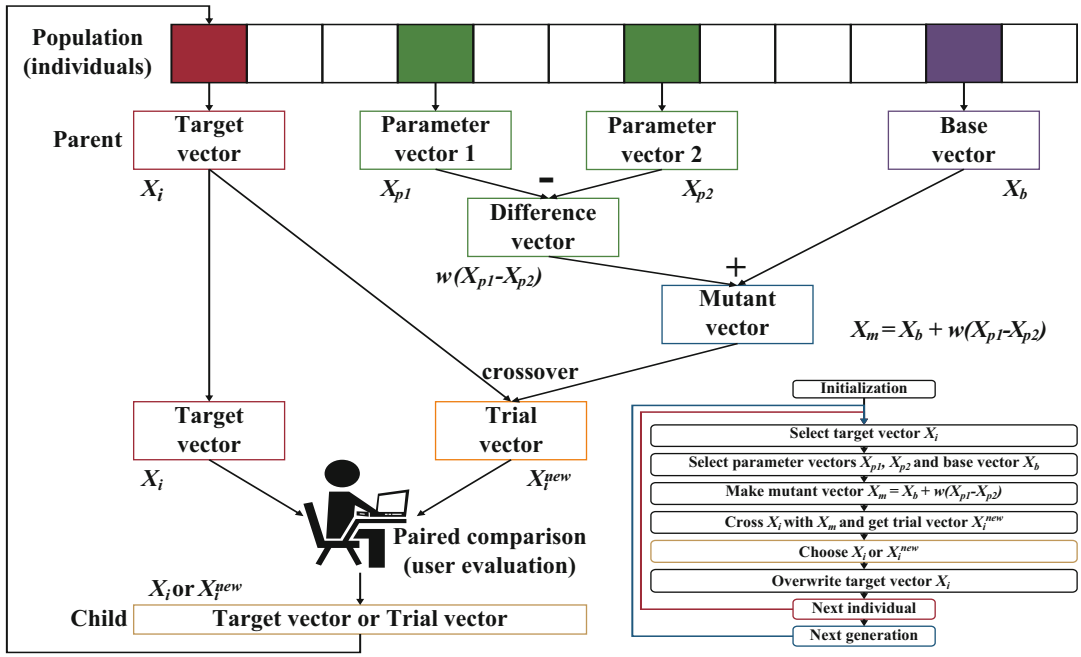
1. The user can use the paired comparison evaluation.
2. It has a good convergence characteristic in a small population.

DE has some formats, and it expresses as DE/base/num/cross. The following are specific formats:

(i) Base: The selection method of a base vector.
- Rand: Select a vector from a parent group of individuals randomly.
- Best: Select the best vector from a parent group of individuals. DE/best has better convergence performance than DE/rand. However, it needs parallel comparison of all individuals to select the best vector.
- Gravity: Select a centrobaric vector from a parent group of individuals. DE/gravity has almost the same convergence performance as DE/best, and it needs not parallel comparison of all individuals (Funaki et al. 2011). However, the convergence performance will deteriorate if the centrobaric vector is quite different from the global optimum solution.
- Moving: This selection method works with another selection method. It makes a moving vector that accumulates the difference between a target vector and trial vector, and it adds the moving vector to the base vector to accelerate the convergence performance.

(ii) Num: The number of difference vectors.

(iii) Cross: The crossover method of a target vector and trial vector.
- Bin: Use the binomial crossover that performs a crossover with a fixed probability.



3D Room Layout System Using IEC (Interactive Evaluational Computation), Fig. 2 The conceptual diagram and flowchart of IDE

- Exp: Use the exponential crossover that performs a crossover with the probability decreases in an exponential manner.

The user evaluates individuals in interactive differential evolution (IDE) as with IGA. Figure 2 illustrates the conceptual diagram and flowchart of IDE. The user selects the target vector or trial vector, and he/she repeats it until the number of evaluated target vectors exceeds the predefined number of individuals to obtain a next generation. IDE reduces the burden of user evaluation because it needs not parallel comparison of all individuals except for DE/best. However, the user needs to compare four individuals in the evaluation stage when used in combination with the moving vector. The user selects a vector from the target vector, trial vector, combination of target and moving vector, and combination of trial and moving vector in this case. In addition, Pei et al. reported that incorporating the opposition-based learning with IDE could improve the quality of group of individuals (Pei et al. 2013) (Table 5).

Examples of the IEC Applications

Many researchers elaborate IEC applications, improving performance and extending application ranges. This section introduces some applications developed in recent years.

Web Page Design Sorn et al. proposed the design system that generates a template for Web page interactively using IGA (Sorn et al. 2013). Although the work of creating and designing Web pages is increasing, they are time-consuming tasks. In addition, users have to learn the programming languages such as JavaScript and usages of authoring tools so that they can create the particular Web page. The proposed system evolves HTML and CSS based on the user preferences, and genes represent the layout expressing a location of navigation bar and styles such as font color and size. It displays ten Web pages as individuals in a generation, and the user gives ratings of one

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 5 Pseudo-code for typical IDE/rand/1/bin

```
IDE ( )
  w = predefined weighting coefficient;
  generation = 0;
  create initial group of individuals;
  REPEAT
    i = 0;
    REPEAT
      x_i = select a target vector from current group of individuals;
      x_p1, x_p2 = select parameter vectors from current group of individuals randomly;
      x_b = select a base vector from current group of individuals randomly;
      x_m = x_b + w * (x_p1 – x_p2);
      x_new = make a trial vector from x_i and x_m by using binomial crossover;
      x_i = USER (x_i, x_new);
      IF user is satisfied THEN RETURN x_i;
      i = i + 1;
    UNTIL i > predefined number of individuals;
    generation = generation + 1;
  UNTIL generation > predefined number of generations;
STOP
```

(good) to five (bad). Furthermore, the user can evaluate each section such as header and footer particularly so that the system reflects the specific user preferences.

Fashion Design Mok et al. proposed the design system that generates a fashion sketch interactively using IGA (Mok et al. 2012). The design aid is useful for increasing productivity. The proposed system has a sketch design model describing the characteristics of the design, a database storing sketch design models, and a multistage sketch design engine that builds the final design. Mok et al. demonstrated the system making the skirts design. Genes represent the silhouette, shape, type of waist and hem, and decoration such as dart, yoke, pleat, panel, gathers, slit, and ruffles. The system generates initial population based on the waist level and skirt length the user decides at the beginning, and it evolves the skirt design.

Refactoring Ghannem et al. proposed the design system that generates a sequence of refactoring interactively using IGA (Ghannem et al. 2013). Refactoring is a technique that restructures existing models such as class diagrams in a software development cycle, and it improves design quality while preserving its semantics. It is difficult to automate a complex refactoring and evaluate the quality and integrity of refactored models because it needs empirical rules. The proposed system incorporates feedback from users into the optimization processing, and it uses the first knowledge obtained from examples of refactoring and the second knowledge obtained from users. The system analyzes the similarities of examples and inserts the second knowledge interactively, and it displays applicable refactoring while optimizing a model. Genes represent the sequence of refactoring operations such as "pull-up method," "rename attribute," and "move attribute." The system applies these operations to compose models and gets the evaluation the user scored using the five-level scale.

3D Motion Akase et al. proposed the design system that generates a 3D motion of the

Avatar interactively using IGA (Akase et al. 2012). Movies and computer games use 3D motions to make the motion of 3D characters. Generally, designers generate 3D motions using motion capture systems. However, it is difficult to create various 3D motions. The proposed system creates a unique 3D motion by considering a physical limitation. It combines the inverse kinematics with IGA to reduce the variables required for motion optimization, reducing the burden of user evaluation effort. The system optimizes the trajectory of end effectors instead of the joint angles. Genes represent the traveling sequences in common with the gene expression of traveling salesman problem. As with the feature Sorn et al. introduced, the user can evaluate each body part such as the head, arms, and legs particularly so that the system reflects the specific user preferences.

Layout Generation

This section introduces the methodologies to create the interactive 3D layout generation system.

Automatic Layout Generation Based on the Constraints

In recent years, designers create city design and room layout in a virtual world. For example, "City Engine" can create cities including street layouts and buildings automatically. Parish and Muller proposed this system, and they use a procedural approach based on L-systems to model cities (Parish et al. 2001).

The layout work for 3D virtual rooms takes a long time because 3D objects have six degrees of freedom. In addition, 3D furniture objects have furniture-specific features. For instance, TV needs some space for its watchers to watch, and desk and chair need pairs generally. These features are associated with ergonomic design. Akazawa et al. proposed a system that generates 3D scene automatically based on contact constraints (Akazawa et al. 2005, 2006). The proposed system makes scenes by using a semantic database. The following are specific attributes of the semantic database:

1. Face: Indicate the surface number of bounding box wrapping the 3D furniture object.
2. Occupancy distance: Indicate the minimum distance not to touch other objects.
3. Parent: Indicate the parent objects.
4. Constraint: Indicate whether a face should touch a certain face of other object or not.
5. Inside component: Indicate the objects placed inside the object.
6. Connection width: Indicate the width number of objects to place them in the rectangular area.
7. Connection depth: Indicate the depth number of objects to place them in the rectangular area.
8. Connection face: Indicate which faces of the bounding box are connectable.
9. Raito: Indicate the ratio of the number of objects in a width direction to the number of objects in a depth direction.

Similarly, Lap-Fai et al. proposed automatic 3D layout systems based on ergonomics constraints (Lap-Fai et al. 2011). They defined ergonomics as follows:

1. Accessibility: Maintain the space for furniture to perform a basic furniture function.
   - For example, bookcases need extra space for books.
2. Visibility: Maintain the sight for human to look viewing surfaces.
   - For example, other objects should not block a television.
3. Pairwise relationship: Maintain the semantic compatibility between objects.
   - For example, place a desk and chair in pairs.

Their system executes the following processes to arrange many objects:

(a) Create relationships between one object and the other: System learns relationships from preliminarily ordered 3D layout.
(b) Optimize the layout: Minimize the number of inappropriate objects that violate the ergonomics constraint using simulated annealing.

Interactive Layout Generation Using the Language and the Real-World Information

Calderon et al. proposed the interactive furniture placement system using the constraint logic programming (Calderon et al. 2003). The user can obtain knowledge and skills of the room layout design by using the system. Similarly, Coyne et al. developed Words Eye that generates 3D scenes using the natural language (Coyne et al. 2001). Words Eye parses several sentences to extract the object information and tags the corresponding label, and it depicts a 3D scene from 2000 shape data and 3D texts.

Alternatively, several studies use a 3D scanner and an RGBD camera to make 3D scene data from the real-world scene information. For instance, Nan et al. and Kim et al. proposed a new method that makes 3D scenes using a 3D scanner (Kim et al. 2012; Nan et al. 2012). In addition, Shao et al. developed the system that searches similar 3D shapes from a database using RGBD camera, making the 3D scenes using them (Shao et al. 2012).

Interactive Layout Generation Using IEC

Color Design

Miki et al. proposed the office design system that uses PDIGA (Miki et al. 2003). The system optimizes the color of office equipment and supplies such as partitions, carpets, tables, personal computers, and chairs. Genes represent the continuous-valued hue and tone, and the system employs the real-coded GA method. The user evaluates the presented color pattern in terms of the preference and a style that suits the working environment using the five-level scale.

Floor Layout

Garcia et al. proposed the IGA-based system that generates the floor layouts of an ovine slaughterhouse and recycling carton plant incorporating the knowledge of expert designer and preference of the user (Garcia et al. 2013). The system uses the flexible bay structure that manages the floor layouts by dividing floor into bay. Genes represent the equipment number used to specify an equipment location and the position of a bay.

3D Room Layout

Akase et al. proposed the IGA-based system that generates the 3D room layouts by a combination of parent-child relationships (Akase et al. 2013, 2014). The system saves the combinations to the

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 6 The build process of combinations

```
maximum_number_of_furniture_objects = 37;
maximum_number_of_patterns = 8;
patterns[maximum_number_of_furniture_objects]
[maximum_number_of_patterns];
makePatternNumbers ( )
  i = 0;
  REPEAT
    object_i = select a furniture objects;
    pattern = {};
    //The system uses this number for genes
    pattern_number = 0;
    REPEAT
      //designer's task
      pattern.parent = select a parent object;
      //designer's task
      pattern.relative_distance = set a
relative_distance;
      //designer's task
      pattern.relative_angle = set a relative_angle;
      patterns[i][pattern_number] = pattern;
      pattern_number = pattern_number ± 1;
    UNTIL
pattern_number > maximum_number_of_patterns;
    i = i + 1;
  UNTIL i > =
maximum_number_of_furniture_objects;
STOP
```

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 7 The build process of room layout

```
maximum_number_of_furniture_objects = 37;
//idx is the index number of an individual
gene_sequences[idx]
[maximum_number_of_furniture_objects];
placeObjects (gene_sequences, patterns)
  i = 0;
  REPEAT
    //select a pattern number (gene element) from a gene sequence
    pattern_number = gene_sequences[idx] [i];
    //get a pattern data
    pattern = patterns[i] [pattern_number];
    //The root parent is "Room"
    IF pattern.parent is not placed THEN
      i = i + 1;
      continue;
    ENDIF
    //place a target object_i
    object_i.position = pattern.parent.position + pattern.relative_distance;
    object_i.rotation = pattern.parent.rotation + pattern.relative_angle;
    i = i + 1;
    IF i > maximum_number_of_furniture_objects THEN
      i = 0;
    ENDIF
  UNTIL all objects are placed;
STOP
```

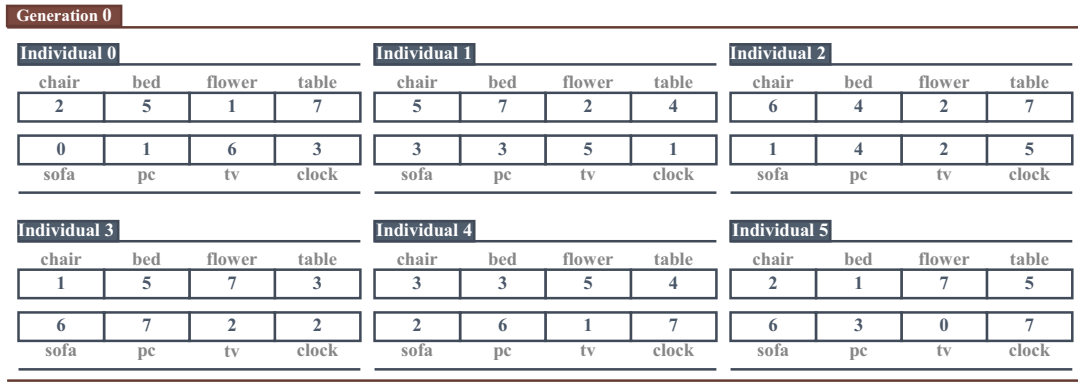
database as with the system Akazawa et al. proposed. Table 6 explains the build process of combinations, and Table 7 shows the build process of room layouts. Genes represent the combination index called "pattern number." Figure 3 illustrates an example of gene sequences, and Fig. 4 indicates a part of evolving process in order of top left to bottom right. It optimizes 3D room layouts based on user evaluations.

Quantitative Evaluation Techniques and Problems of the IEC-Based Systems

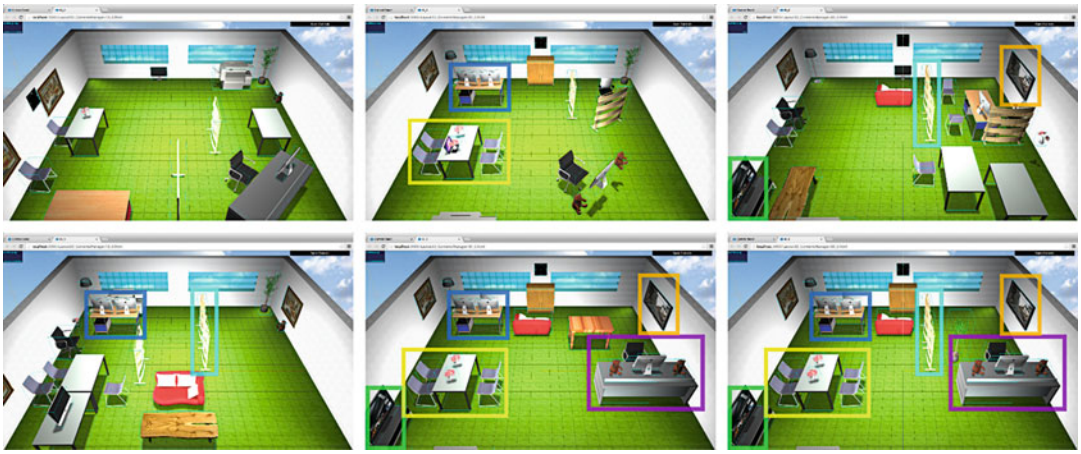
Quantitative Evaluation of the IEC-Based Systems

It is difficult to measure performance of the IEC-based system in a quantitative way because it includes the subjectivity of users. Many studies perform a perceptual study using actual users to receive a questionnaire about the usability and logs of fitness, and they evaluate the usefulness of the IEC-based system applying a statistical test to them. The following are specific assessment procedures:

1. Set the goal individual (concept) users should create.
2. Conduct the experimental tests using actual users.
   (A) Create the goal individual using an authoring tool manually.

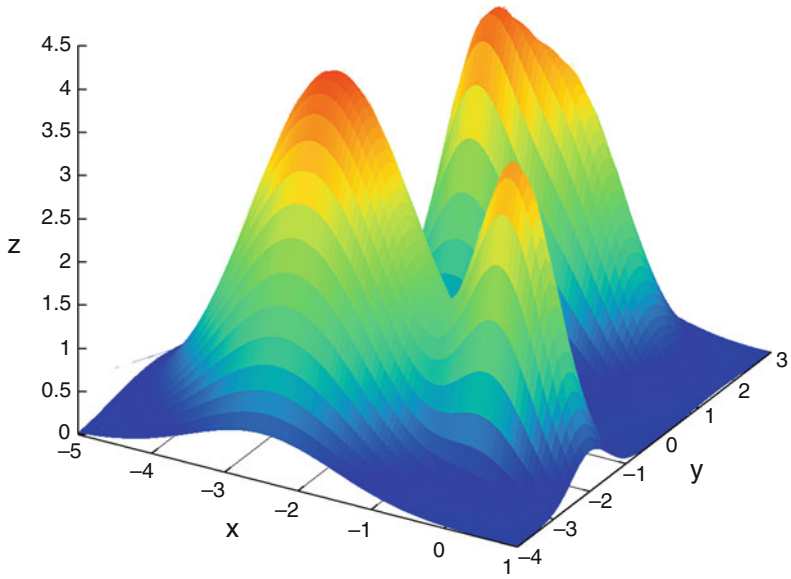


3D Room Layout System Using IEC (Interactive Evaluational Computation), Fig. 3 An example of gene sequences



3D Room Layout System Using IEC (Interactive Evaluational Computation), Fig. 4 A part of evolving process in order of *top left* to *bottom right*

3D Room Layout System Using IEC (Interactive Evaluational Computation), Fig. 5 Mixture Gaussian function



(B) Create the goal individual using the IEC-based system interactively.

3. Subjects select A or B that let them create the goal individual easily.
4. Calculate statistically significant difference between A and B.

Takagi et al. proposed a performance evaluation method for IEC algorithms (Takagi et al. 2009). It represents a psychological peculiarity of an IEC user using a mixture Gaussian function consisting of four Gaussian functions. The following are specific function and parameters, where n is the dimension number (Fig. 5):

$$\mathrm{f}\left(x_1, \ldots, x_n\right) = \sum_{i=1}^{4} a_i \exp\left(-\sum_{j=1}^{n} \frac{\left(x_{ij} - \mu_{ij}\right)^2}{2\,\sigma_{ij}^2}\right)$$

$$\mathrm{a} = \begin{pmatrix} 3.1 \\ 3.4 \\ 4.1 \\ 3 \end{pmatrix},$$

$$\mu = \begin{pmatrix} -1 & 1.5 & -2 & -2.5 & -1 & 1.5 & -2 & -2.5 & -1 & 1.5 \\ 0 & -2 & 3 & 1 & 0 & -2 & 3 & 1 & 0 & -2 \\ -2.5 & -2 & 1.5 & 3.5 & -2.5 & -2 & 1.5 & 3.5 & -2.5 & -2 \\ -2 & 1 & -1 & 3 & -2 & 1 & -1 & 3 & -2 & 1 \end{pmatrix}$$

$$\sigma = \begin{pmatrix} 1.5 & 1.5 & 1.5 & 1.5 & 1.5 & 1.5 & 1.5 & 1.5 & 1.5 & 1.5 \\ 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 \end{pmatrix}$$

Problems of the IEC-Based Systems

The maximum limit both of the number of individuals and generations is around 10–20 due to a burden of the user evaluation effort in the IEC-based systems (Takagi 2001; Takagi et al. 2009). Therefore, developers have to consider the following:

1. Improve the convergence speed of group of individuals.
   - In general, it depends on an evolutionary computing algorithm.
2. Support the user evaluation effort.
   - Improve the IEC user interface and evaluation method.
   - Incorporate an agent that predicts the fitness based on the characteristics of IEC users.

The effective algorithms such as PDIGA, IDE, and their derived type are addressing the first problem as the previous section explained. This section introduces some support methods to reduce a burden of the user evaluation.

Improvement of the IEC User Interface

The system Garcia et al. proposed clusters individuals, and it displays some representative individuals to the user at least in the early generations (Garcia et al. 2013). It employed the fuzzy c-means clustering algorithm (FCM) Bezdek et al. proposed (Bezdek et al. 1984). Each individual can belong to some clusters because the FCM allows overlapping of clusters. This feature can help the user evaluation because the individuals that the user did not evaluate can get scores from evaluated individuals belonging to a same cluster.

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 8 The procedure of proposed system

```
MAIN ( )
  p = predefined weighting coefficient;
  priorities, elite = CONJOINT_ANALYSIS ();
  generation = 0;
  create initial group of individuals;
  REPEAT
    //Function C checks the constraints associated with priorities
    fitness = (1 – p) * priorities * C (current group of individuals)
      ± p * USER (current group of individuals);
    IF user is satisfied THEN RETURN the best individual;
    i = 0;
    REPEAT
      select two individuals based on fitness;
      //maintain upper two individuals
      apply elitist selection;
      //produce new two individuals
      perform crossover;
      //produce new two individuals based on the elite individual
      perform crossover with elite;
      perform mutation;
      insert six offspring into new group of individuals;
      i = i + 6;
    UNTIL i > predefined number of individuals;
    generation = generation + 1;
  UNTIL generation > predefined number of generations;
STOP
```

3D Room Layout System Using IEC (Interactive Evaluational Computation), Table 9 The procedure of conjoint analysis

```
CONJOINT_ANALYSIS ( )s
  cards = predefined renderings;
  REPEAT
    scores = USER (subset of cards);
    averages = calculate_average (subset of cards, scores);
    deviations = calculate_sum_of_squared_deviation (subset of cards, scores, averages);
    products = calculate_sum_of_products (subset of cards, scores, averages);
    solution = solve_system_of_equations (deviations, products);
    priorities = calculate_priority (solution);
    expectancies = calculate_expectancy (cards, solution);
    elite_individual = select_best_card (cards, expectancies);
    precision = check_precision (scores, expectancies);
  UNTIL precision > = 0.5;
  RETURN priorities, elite_individual;
STOP
```

Analysis of the Characteristics of IEC Users

The system Akase et al. proposed analyzes user preferences using a conjoint analysis so that it can support user evaluations and reflect user preferences effectively (Akase et al. 2014). The conjoint analysis is an experimental design method that gets user evaluation values from some rendering and returns the characteristics of users. Tables 8 and 9 and Fig. 6 explain the procedures of the proposed system. The system generates offspring around the elite individual selected by the conjoint analysis. In addition, the individual that fits the potential user preference analyzed by the conjoint analysis gets an additional score from the system automatically. These features can accelerate the convergence speed.

Summary

This entry introduced the typical IEC algorithms, generation methods of layout, and recent IEC applications. In addition, it indicated the problems of the IEC-based systems and some solutions for future directions. Although the burden of the user evaluation to optimize complex contents such as 3D room layout that has many parameters is a problem, many researchers are addressing it. An IEC-based authoring tool could be a practical product if they resolved the problem completely.

Definition

Selection is a prerequisite task for object manipulation in 3D user interfaces. The virtual object must obey specific conditions to be considered the targeted object for selection. This article explores the existing selection techniques for the

distant object in an augmented reality environment.

Introduction

Recently, augmented and mixed reality (AR/MR) application has become more popular among researchers, businesses, and developers in presenting the information. As current technologies have improved and are capable of AR and MR, more interesting and improved applications are developed to meet users' needs. In AR and MR, selection has been the common task in performing interaction with virtual objects that is being superimposed on the real-world environment. According to Mine (1995), selection is considered when an object is being pointed and validated among other objects available. The selection is important to be precise in order to select the targeted object in the scene correctly. Therefore, various approach has been taken by the previous researchers in order to overcome this issue. Meanwhile, according to Yin et al. (2019), the issue of defining suitable and propitious 3D interaction techniques is still an agile area of study.

Milgram continuum, a reality-virtuality continuum, has sufficient reference for the framework regarding the classification of different immersive technologies. The continuum depicted MR as a transition between the actual and virtual worlds, including AR with augmented virtuality (AV) placed in between (Milgram and Kishimo 1994). The blending of real and virtual worlds creates new surroundings and visualizations, allowing for an immersed user experience, which refers to the quality of the interactions given to the user. Meanwhile, AR enables the visualization of virtual objects in conjunction with real-world scenes via mobile devices such as smartphones and tablets, including AR glasses and head-mounted displays (HMD) (Silva 2018).

With the current advanced technology, AR applications in mobile devices are more approachable, allowing them to bloom and enable various applications widely. In the early stage of AR, AR was first used for entertainment in the form of games. Still, it is now being used in a variety of areas, including education, healthcare, training, remote collaboration, maintenance assembly, and smart manufacturing (Barrie et al. 2019; Birt et al. 2018; Peña-Ríos et al. 2012; Richert et al. 2019; Stretton et al. 2018). Selection for the target object in AR and MR will allow the interaction to be more precise and therefore enable a more complex interaction within the application.

In this context, this article presents and discusses the overview of the selection techniques proposed by previous researchers for the target object in MR to improve the interaction between the users with the target object in the environment.

Background

3D interaction techniques have been extensively researched in immersive virtual environments using HMDs and tracking devices, including data gloves and on desktop setups with a keyboard and mouse (Yin et al. 2019). Bowman et al. (2004) investigated the interaction techniques commonly used in 3D user interfaces and created a taxonomy of universal tasks for interacting with 3D virtual environments: selection and manipulation of virtual targets; navigation and path findings inside a 3D environment; giving instructions using 3D menus: text, tags, and legends are examples of symbolic input. Meanwhile, several studies have explored the attributes that improve the usefulness of 3D user interfaces, mainly for desktops and near-to-eyes displays. They have proposed a general guideline to UI developers. Better use of depth cues, especially occlusion, shadows, and perspectives, as well as considering the constrained angle of the viewpoint position, object being in contrast with the surroundings, and other factors, are included among the guidelines.

Therefore, accurate selection plays an important part in providing education and information exchange among academics, companies, and developers. For a more pleasant overall experience, applications like entertainment and gaming require more interaction for the user. While for

commercial uses such as healthcare or business training, there is a need for a feeling of physical presence to be more effective with the interaction and enable accurate selection.

Several input alternatives currently exist and has been proposed by previous researchers in performing selection and further interaction with the virtual objects such as touchscreen-based inputs, gesture-based input, inertial device-based input, speech-based inputs (Lee and Chu 2018; Mossel et al. 2013; Połap 2018; Su et al. 2018; Yusof et al. 2020). However, gesture-based input is described as the most natural and intuitive approach in performing selection to interact with the virtual object. Interaction with natural gestures in free space enables possibilities for exploiting the interaction's fullness and expressive-ness, allowing the users to manage several things at once with more degree of freedoms (DoFs) and utilize the familiar and real actions (Argelaguet and Andujar 2013). Furthermore, interaction using natural gestures is the most familiar action for the users, which mimics the actions in daily life.

Besides that, the brain-computer interface (BCI) is another field that has sparked researcher's interest in enabling a new way of interaction in the AR/MR environment (Si-Mohammed et al. 2017). BCI is a system that takes a biosignal, measured from a person, and predicts (in real-time) certain aspects of the person's cognitive state. BCIs could particularly contribute to AR-based systems interaction means, especially on visual selection tasks that can be done, as an example, via steady-state visually evoked potentials (SSVEP) or P300 (Gergondet et al. 2011). With the high computational power of current computers and display devices, the goal to build a real-time adaptive system for AR has been made a lot more reachable (Vortmann 2019). Recently, the NextMind (www.next-mind.com) company has developed an affordable brain device with a novel type of SSVEP stimuli that is less straining on the eye. For example, Pietroszek et al. (2021) has utilized NextMind within their experiment with AR HMD to allow for derogating experience, where the player picks up and moves the pieces and rolls the dices using their brainwaves as input. With the availability of such device/technology, more possibilities of interaction or other research intention can be explored in various fields with the implementation of AR and MR.

There are various reasons on precise selection for the distant object is needed. Since AR and MR are becoming more prevalent in data or information presentations, it is essential to provide an accurate selection for better interaction between the user and the object in the system provided. To define precise selection, the time taken for the selection to be complete should be less, enabling a higher speed for the interaction to complete. With accurate selection, a more precise result of the interaction can be provided.

However, previous researchers have addressed several challenges on achieving selection for smooth interaction with the virtual object. Whitlock et al. (2018) have addressed interacting with distant objects in AR. Aside from that, pointing accuracy may be affected by variations of in-depth perception for real and virtual objects (Whitlock et al. 2018). Ro et al. (2019) also highlight the issue of selection on a distant object with limitations on devices such as see-through HMD (e.g., Hololens), where it requires the object to be within reach (limit distance reachable by the user) for it to be selected. Other challenges are that pointing to obscured target objects in noisy surroundings may need nonlinear visual and spatial mapping (Olwal and Feiner 2003). Therefore, previous researchers have proposed various approaches to address these issues.

The following section discusses the approaches from previous researchers on the selection techniques for a target object in AR/MR to enable and improve the interaction between the user and the target object in the environment.

3D Selection Techniques

According to the study by Argelaguet and Andujar (2013), interaction is more physically challenging within the 3D environment and may

obstruct user tasks by requiring greater skill. Their study has identified two main 3D selection metaphors: virtual hand and virtual pointing. The virtual hand is a common metaphor for interacting with objects in an immersive environment. It enables interactions with objects, which are within the arm's reach of the user. With virtual hand metaphor, objects are being interacted with in a manner that is similar to touching and grasping in real life. Virtual hands are often implemented as a one-to-one mapping of the user interaction area (the region of space that the user may reach, such as within arms reach of the user) and the control area (the space reachable by a virtual hand in the immersive system). On the other hand, virtual hands are typically less accurate and result in delayed task completion than the alternative technique, virtual pointing, owing to existing technology implementations.

Although the virtual hands technique is well-known at the beginning since it directly maps the virtual tasks identically with the actual task, which results in a more natural interaction. However, current researches have demonstrated that tackling real-world bodily constraints has significant advantages, such as allowing the selection on the out of reach objects to be performed by the user using raycasting, a pointing technique. According to a number of user analyses in the literature, virtual pointing techniques generally result in higher selection efficacy than rival 3D selection metaphors (Bowman et al. 2004).

Ray Pointing

The raycasting technique can be implemented for touch-based interaction, gesture-based interaction, or hybrid interaction. Raycasting can also be implemented in various aspects, including how the ray is being controlled. Raycasting extends the user's reach by pointing an extended ray outwards, starting at the user's hand or the designed cursor (Auteri et al. 2013). A starting point and a trajectory are required to control the ray. These two values may be obtained by monitoring the orientation and position of a controller, the hand of the user, head, or a combination of both. However, the most common approach is often by confirming selection with a button.

A study by Mossel et al. (2013) has presented DrillSample, which addresses the requirements for precise selection with a one-handed handheld interaction in a dense AR surrounding. Other than that, they also address issues of disambiguation and selection in a dense mobile AR environment for highly occluded objects or with high visual resemblance. In their approach to perform precise selection in touch-based interaction, a single touch action on the screen causes the coordinates of the 2D screen to be projected back into the 3D space. It will trigger the ray to be cast from the virtual camera's position in the direction of the 3D point into the handheld AR scene. The handheld device 6DOF stance, which is generally provided in handheld AR, may be used to estimate the direction.

Meanwhile, Ramos et al. (2015) presented GyroWand, a 3D interaction with the implementation of raycasting technique in independent AR HMDs. The inertial measuring unit (IMU) on a handheld controller captures relative rotation data utilized in the raycasting technique.

Another study by Ro et al. (2019) has proposed a new user interface that utilizes raycasting using the depth-variable method for selection on remote objects in an AR environment. The ray-depth information is included in addition to sensor information because ray-depth must be adjusted for pointing in mid-air in a 3D space. Although GyroWand is also utilizing IMU on a handheld controller to capture the relative rotation data for the raycast for the selection, however unlike the AR pointer, it did not have depth information. The GyroWand will go into the *Disambiguation state,* where users refine the actual target they want to select in-depth. Aside from that, the GyroWand was able to employ the ray as a line and convert it to a volumetric form if required. It will improve precision while choosing items at a distance.

Flexible Pointer

Apart from that, Olwal and Feiner (2003) have suggested a flexible virtual pointer that permits a user in a 3D world to more readily point towards

completely or partly covered targets and further clearly identify things to other users. The flexible pointer reduces ambiguity by avoiding concealing objects that might have been chosen if using traditional raycasting techniques. The flexible pointer is implemented as a quadratic Bézier spline, with three points (position, endpoint, and control point) in 3D space controlling its location, length, and curvature.

Go-Go Gesture Technique

Other than raycasting, Go-Go is another basic approach to perform selection on the target object (Poupyrev et al. 1996). Although Go-Go performs poorly in dense settings when picking objects, it can readily choose entirely occluded objects in a single step. In the Go-Go technique, the selection is done by extending the virtual hand towards the target object. A study by Jung et al. (2017) has proposed BoostHand in which they modify The Go-Go interaction technique into one that can be switched using easy trigger actions. The Go-Go interaction approach utilizes a preset mapping function to easily manipulate virtual objects with a virtual hand avatar. The interaction is intuitive and natural since it makes use of the natural hand, requires little training, and performs the functions of selecting (grabbing) and manipulating (translation, rotation, and scale) in real-time.

A study by Yin et al. (2019) has addressed the issue of selecting occluded target objects with touch-based interaction. Touch-based interaction is one of the most natural and attractive input forms for handheld interfaces because it allows users to interact directly with the target object. Other than that, they also address the issue of the small area for interaction, as the display screen is limited. Therefore, their study discusses four novel 3D selection techniques with Go-Go and Raycasting techniques as the baseline to overcome these issues. After pointing at an object at a distance (laser pointer metaphor) and intersecting the ray, the user may select the object using other actions (button selection, gesture, or speech) (Ro et al. 2019). However, it becomes less intuitive and natural than the real hand manipulation method.

Hybrid Technique

Meanwhile, a study by Kim and Lee (2016) proposed a hybrid interaction technique that combines touch-based with real hand gesture-based interaction to perform a selection for further interaction with objects in the environment. The selection of the AR object is completed with a touch gesture, while a real hand gesture is enabled for manipulation of the selected objects directly and interactively. As a result of the hybrid interaction, the user will be able to perform interactions such as manipulation on the AR targets in actual 3D space rather than 2D space.

Due to calibration flaws and tracking system constraints, eye gazing may be quicker and more ergonomic for selecting the target object, but it has poor precision. As a result, researchers have developed multimodal techniques that improve eye-gaze selection using a supplementary input modality that will refine the selection process. For example, the target selection technique presented by Kytö et al. (2018) implements selection techniques with a multimodal approach, using eye-gaze or head-motion. To achieve pinpoint precision, these techniques use rough pointing selection accompanied by a secondary, local refining action. Each primary selection mode is able to combine with any refinement method. Their research is limited to 2D surfaces, such as those implemented in selecting the menu, interactive visualization, and in-situ CAD application.

Furthermore, multimodal input is seen as a way to increase the interactions of virtual and real-world components. Because it allows for simultaneous interaction within the physical and virtual worlds, the interaction approach is suitable for AR applications (Ismail and Sunar 2015). Meanwhile, speech input is often implemented as a hybrid technique combined with gesture-based or gaze-based for interaction with objects in AR and MR environments. Speech has been shown to be an ideal choice for abstract actions, such as selecting a device among many devices or interacting with multi-object (Piumsomboon et al. 2014; Zaiţi et al. 2015). The advantages and drawbacks of the 3D selection techniques of related researches discussed in this article are summarized in Table 1.

3D Selection Techniques for Distant Object Interaction in Augmented Reality, Table 1 The summary of 3D selection techniques of related researches

Researchers	Proposed selection technique	Advantage	Drawback
Ro et al. (2019)	AR Pointer – Able to specify ray direction and adjustable ray's depth to calculate the ray's endpoint	Easy to learn for the user and fast completion time Able to register an object at a specific mid-air point in three dimensions	The error rate is higher for object rotation angle error (arc ball rotation method)
Yin et al. (2019)	Present four novels AR selection techniques for handheld mobile devices.	Although tested in a handheld AR environment, it can also be applied in other dense virtual environments or other interactive interfaces that use touch screen input	The technique presented was only implemented for selection using touch-screen input
Kytö et al. (2018)	Multimodal pointing techniques for wearable AR interfaces. Presented two prototypes – GazeBrowser and SmartPupil	Include two primary input modes, eye gaze and head pointing, and combine with a refinement provided by a handheld device	Gaze calibration was typically less accurate for extreme upper and lower targets, and that overall accuracy tended to degrade over time
Jung et al. (2017)	BoostHand – a freehand, distance-free object-manipulation system that supports simple trigger gestures using Leap Motion	The user control space can be expanded by emphasizing intuitive and straightforward interaction Able to provide better performance at long distances with fewer movements	Tracking errors by Leap Motion can largely influence the system's performance
Kim and Lee (2016)	Hybrid interaction of touch-based and real hand gestures for direct interaction with AR objects	Enable natural and intuitive interaction with 3D AR objects on handheld and mobile devices	One hand needs to hold the device, which could lead to fatigue.
Ramos et al. (2015)	GyroWand – interprets the relative rotational values using a state machine and provide three new disambiguation mechanisms	Initiate raycasting from other spatial coordinates (chin is a good candidate as the origin for the raycast)	Does not investigate the performance and comfort of the proposed approach against the natural user interface
Piumsomboon et al. (2014)	G-SIAR – multimodal interaction technique of gesture and speech	G-Shell required less effort, frustration, mental, physical, and temporal demand, and provided higher performances	There are limits in the tracking resolution and speech and gesture recognition accuracy
Auteri et al. (2013)	Presented a hybrid selection technique that combines PRISM and Go-Go	Enumerated different design decisions involved blending PRISM and Go-Go, resulting in a huge improvement in task precision	The user felt a lack of control when using PRISM
Mossel et al. (2013)	DrillSample – two-step selection technique with only one finger input in a dense handheld environment (high visual similarities)	Develop guidelines to enable precise selection in a single-handed handheld AR environment The performance study clearly revealed the strength of the DrillSample technique compared to related work in the study	It was only tested for selection on the occluded object within close range

Conclusion

Over the last decade, the topic of selection on the target object has been in the interest of researchers and developers from various fields of studies in AR and MR. It shows that selection still plays a vital role in interaction with the target object in AR or MR environment.

Selection as the basic task in performing interaction with the virtual object must be as precise as possible. With preciseness, it will allow a faster and smoother interaction between the user and the virtual content. Selection techniques can be provided in several techniques such as raycasting, Go-Go, or hybrid techniques. Raycasting is a technique for aiming objects from afar with limits for object manipulations like translation and rotation. Meanwhile, Go-Go produces better results when selecting the occluded target object. However, a hybrid technique such as combining touch-based and gesture-based for selection and further interaction with the target object could offer an intuitive and regular interaction in the AR surroundings. While in the MR interface, occlusion becomes an issue when real hands have covered the virtual object. As an advanced selection, Aladin et al. (2020) has explored the occlusion-hand gesture in MR to perform a precise selection technique using the real hand gesture in MR.

3D Visualization Interface for Temporal Analysis of Social Media

Masahiko Itoh
Institute of Industrial Science, The University of Tokyo, Tokyo, Japan

Definition

3D visualization interface for temporal analysis of social media is the interface for visual analytics of various types of time varying media

contents using 3D information visualization techniques.

Introduction

Social media such as blogs and microblogs has become popular. It enables us to easily and rapidly publish information on our personal activities, interests, and opinions through writing document, creating links to other information resources, and providing images and/or movies. It dynamically reflects real movements in society.

Many organizations have collected and archived social media contents over the long term. Time series of archived data enable us to analyze temporal changes in trends in social media that reflect both real and virtual activities.

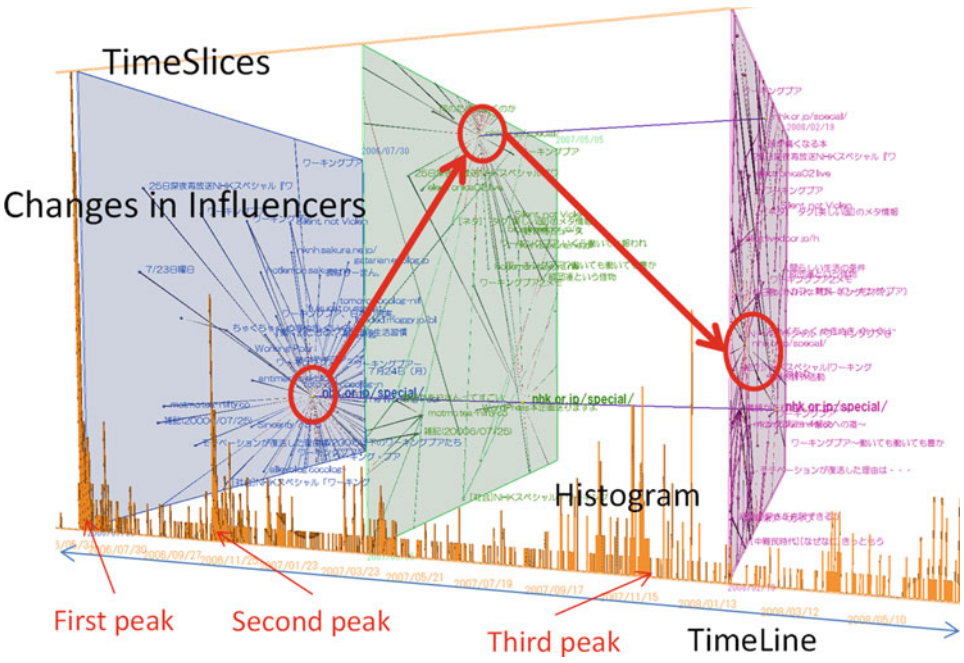
Visual analytics for extracting trends and reading stories from time sequential data sets are important research domains. There has been much research on analyzing temporal changes in trends on social media through visualizing link structures, results of text analysis, or flows of images (Kitsuregawa et al. 2008; Chi et al. 1998; Chi and Card 1999; Toyoda and Kitsuregawa 2005; Kehoe and Gee 2009).

In this entry, I will introduce three kinds of 3D information visualization systems for analyzing temporal changes in: (i) link structure, (ii) textural contents, and (iii) image contents on social media.

State-of-the-Art Work for Visualizing Temporal Changes in Social Media Contents

Visualization for Temporal Changes in Link Structure

We first introduce an interactive 3D visualization system for the time series of web graphs (Itoh et al. 2010). It is to enable us to examine the evolution of web graphs by comparing multiple graphs that have different timings and topics. To accomplish the system, it utilized interactive 3D components called TimeSlices that are 2D planes to visualize web graphs in a 3D environment. We



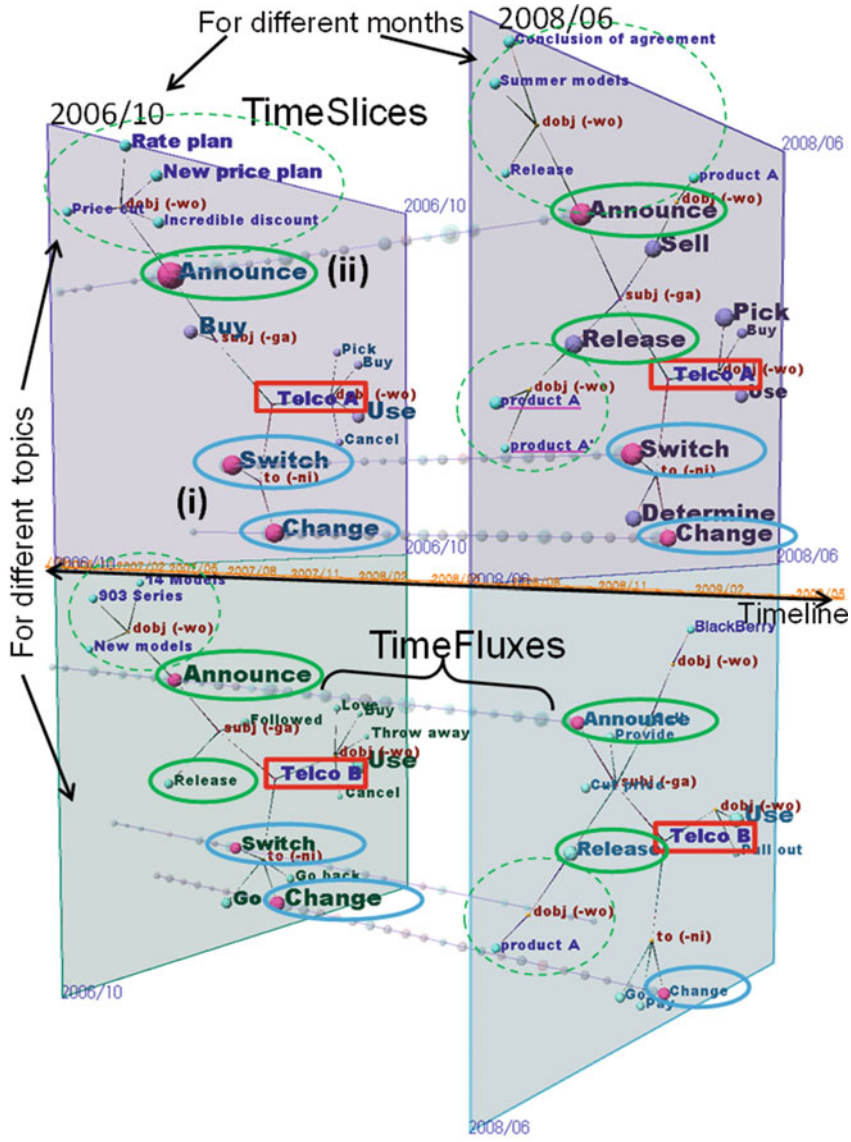
3D Visualization Interface for Temporal Analysis of Social Media, Fig. 1 Example for visualizing changes in link structure on blogs related to the term "working poor"

can interactively add new TimeSlices along the timeline, and they can manipulate them to animate web graphs. Visualized web graphs on TimeSlices are snapshots of different timings.

Figure 1 shows the example for visualizing changes in link structure on blogs related to the term "working poor." First peak appeared after the TV program called the "working poor" had been broadcast. Most blogs were linked to the official page of the TV program. The second peak appeared after the "working poor II" had been broadcast. We can find that influencers shifts in focus from the official pages of "working poor" to "working poor II."

Visualization for Temporal Changes in Textural Contents

We next introduce an interactive 3D visualization system for exploring temporal changes in bloggers' activities and interests through



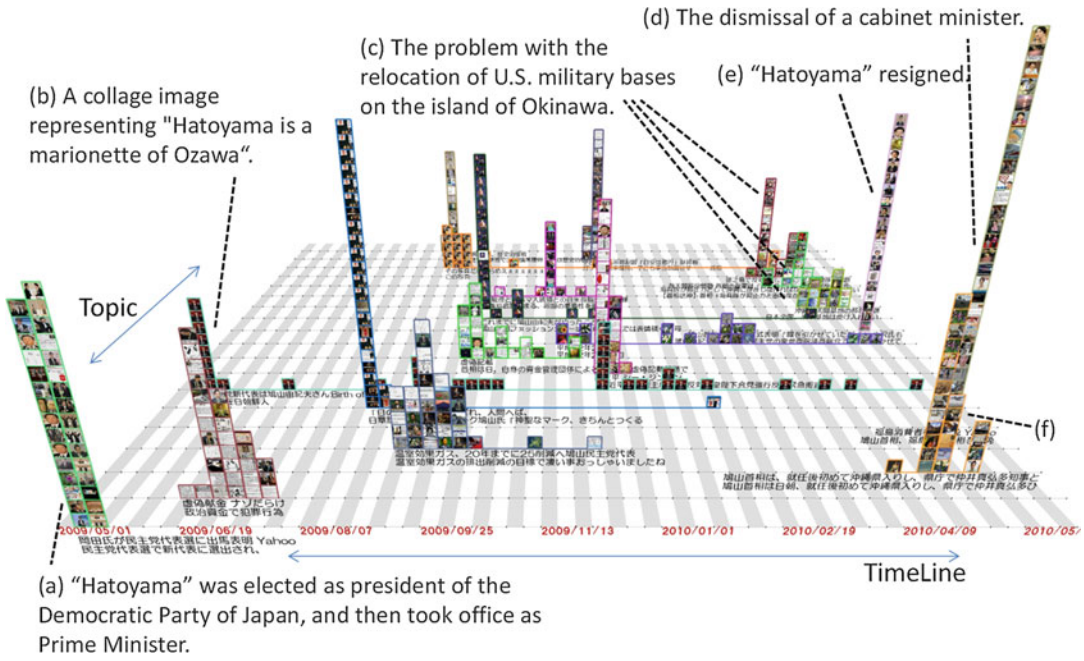
3D Visualization Interface for Temporal Analysis of Social Media, Fig. 2 Example for visualizing changes in textural contents on blogs for comparing marketing effect of two telcos

visualizing phrase dependency structures (Itoh et al. 2012). To accomplish the system, it utilizes two 3D components such as TimeSlices and TimeFluxes. TimeFluxes enable us to visualize temporal changes in the attribute values of particular nodes at every timing. The system visualizes dependency structures of phrases as a unified tree representation in TimeSlices and enables us to interactively navigate to the detailed information by expanding nodes in the tree representation. Sliding operation for the TimeSlices along the timeline indicates changes in the structure and frequencies of dependency relations. To compare different timings and topics side by side, it provides multiple 2D planes. It also visualizes changes in the frequencies of dependency relations by using TimeFluxes.

Figure 2 shows the example for visualizing changes in textural contents on blogs for comparing marketing effect of two telcos. The upper TimeSlice shows a topic for "Telco A," while the lower one shows a topic for "Telco B." (i) We can recognize events related to "change/switch to Telco A" are more popular than "change/switch to Telco B" in most months by observing changes in the structure and frequencies for events. (ii) We can expand nodes related to "announce" and "release" to find details on announcements and products that were released, and we then find that "Telco A" announced a "new price plan" in the first peak and released "product A" in the second peak.

Visualization for Temporal Changes in Image Contents

We finally introduce a 3D system for visualizing visual trends on social media that chronologically displays extracted clusters of images on blogs (Itoh et al. 2013). The system first adopts a histogram of images by stacking them on a timeline to visualize the flow of various images at each timing to visually analyze trends. This design enables us to find the timing for the beginning of the topic, changes in trends for the topic, bursting points, and a lifetime of the trends. Secondly, it arranges multiple histograms of images in a 3D space to visualize images on different aspects. This design allows us to observe different situations between



3D Visualization Interface for Temporal Analysis of Social Media, Fig. 3 Example for visualizing changes in clustered images related to "Prime Minister Hatoyama" extracted from blogs

different topics, sequences of trends, and events with the same timing on different topics.

Figure 3 shows the example for visualizing clusters of images related to "Prime Minister Hatoyama" extracted from blog based on visual, textual, and chronological similarities. The top 20 clusters are arranged from front to back according to their rankings. Images are aggregated per week. We can read stories about "Prime Minister Hatoyama" by exploring the movements of topics.

Conclusion

This entry has introduced the 3D visualization systems for analyzing social media that utilized one dimension in a 3D space as a timeline. Although they independently visualized temporal changes in link structures, results of text analysis, and image clustering for single medium, we can combine these contents and mechanisms to construct integrated 3D visualization systems for intermedia analysis.

3D-Rendered Images and Their Application in the Interior Design

Petyo Budakov
New Bulgarian University, Sofia, Bulgaria

Synonyms

Depth of field; Interior design; Length of view; Lens; Real estate photography; Render; Virtual camera; V-ray, 3D studio max

Definitions

Aperture	This is the hole through which light enters the camera. Its size can be changed to control the brightness of the light allowed through to the image sensor.
Depth of field (DOF)	It determines the depth of field as a range of scene depths that appear focused in an image.
Field of view (FOV)	It illustrates what angle is captured by the lens. The size of the FOV is designated in mm.
Rendering	The process of image synthesis by simulating light environment. The rendering process is performed by render plugins.
Shutter	The shutter speed setting determines how long the shutter remains open to expose the image sensor, e.g., it controls the length of the exposure.
V-ray	It is a render plugin which adds some additional features to the existing software such as: 3D Studio Max, Maya, Blender, Rhynoceros 3D.

V-ray Physical Camera	The camera is the tool that captures virtual 3D image/s.

Introduction

Many interior designers aim to improve the effectiveness of their workflow by reducing the workload they spend to prototype certain products and to dramatically increase the "wow" effect of their final output. The creation of a "dream home" is a major goal to every practitioner whose projects reflect the clients living preferences by lining up shapes, forms, color palette, finishes, textures, and lights. Our fast-paced digital life has changed the consumer's perception and requirements by making it much more sophisticated. The traditional two-dimensional hand-drawing sketches provide certain restrictions regarding the client's imagination by not being able to realistically recreate the real space.

However, the hand-drawing rendering (sketches) laid the basis of the contemporary 3D design and they facilitate the interior designers in building the main foundation of their projects (Wang 2002, p.12): "The real understanding of pencil sketching goes beyond the "state of the art" – it is about creative seeing, such as how to isolate or highlight details in a complex visual scene." Sketching plays a significant role in designer's eye-hand coordination (Wang 2002). People naturally see, observe, and create their projects and the pencil sketching enable the designers to conceive some fresh concepts and to come up with innovative ideas. Thus, sketching as a method could be deemed as a vital prerequisite stage of the workflow rather than an "obsolete" and useless approach.

Recently conducted research study, published by marketsandmarkets.com argues the 3D rendering is expected to grow in a frenetic rate: from USD 1.06 billion in 2017 to accumulate USD 2.92 billion by 2022, at a compound annual growth rate (CAGR) of 22.40% during the forecast period. Many experts are convinced that the usage of 3D visualizations refine the interior design projects as a real showcase of what actually the future home could be without any distortions or including some redundant details.

In order to explore the application of 3D-rendered images in the interior design is important to explain the 3D rendering as a process.

In the real world, the light sources emit photons that travel in certain direction until they interact with a surface. When the photon hits a side, it might be absorbed, reflected, or transmitted. Some of the photons that hit the retina of the viewer are converted into a signal that is perceived by the brain and thus – creating an image. The creation of an image which is based on the same interaction between photons and a 3D environment might be simulated on the computer. The process of image synthesis by simulating light environment is called rendering (Walia 2010). An array of research has been conducted, focused on the following problems:

- How to achieve high quality rendering that induces the feeling of photo realism?
- How to reduce the rendering time?

Rendering Techniques

However, the rendering techniques could be classified into two main approaches (Verma and Walia 2010):

- Geometry-based rendering – the illumination of a scene has to be simulated by applying shading models. This method requires more computing power.
- Image-based rendering – using images as a modeling primitive.

Principles in the Interior Design

The initial stage of project planning includes planning of partitions, furniture layouts, finishes, etc. This process is based on following some specific rules which might seem quite universal for all types of design, e.g., graphic design, fashion design, etc. These rules are determined by Erica Swanson as: balance, emphasis, proportion and

scale, harmony and unity, the rhythm (Swanson 2010).

- Balance
- Emphasize
- Proportion and scale
- Unity and harmony
- Rhythm

Experienced designers often break these rules or create their own in terms of what they insist to achieve. However, in order to illustrate the final outcome, the real estate marketing utilizes the photography as an appropriate manner to present the completed property and its features. The investigator illustrates below the ten most essential and vastly popular principles in real estate photography, determined by Lohrman (2014):

1. Clearly illustrate the features of the estate.
2. Use wide-angle lens.
3. Remove the clutter shadow.
4. Take a primary exterior shot.
5. Illustrate the interior as light and bright – it refers to the exposure control settings.
6. The property's walls must look straight.
7. Vertical and horizontal lines must be also straight.
8. Avoid the brightness of the windows which causes distraction.
9. Simplify the color palette.
10. Present the photo in the most effective way.

The usage of 3D software could facilitate the implementation of these principles by assuring a set of tools that allows designers create, modify, insert objects and textures, adjust the lighting scheme, point of view, and render the final image in a resolution that is suitable for different purposes. Moreover, the 3D modeling and rendering could provide clients with more realistic perspective of the space, to let them decide whether certain furniture fits with the space or not as well as to identify certain flaws. Once these faults are identified, the designers could discuss with their clients how to resolve the problem and come up with an appropriate solution without losing time later.

By using 3D renders, interior designers would be able to simulate how different furniture, finish, wall textures interact with the environment and the main light sources.

3D modeling and texturing enable interior designers easily adjust the space, colors, lights sources, and textures according to clients' preferences. Furthermore, the 3D modeling and rendering allow relatively quick customization and modifications after receiving the clients review. This process significantly increases the effectiveness of the interior design by facilitating the relationships between designers and clients.

However, rendering algorithms are rather complicated and the accomplishment of high realistic 3D images often could be a highly time-consuming process. It might require some special hardware features, based on the fact that rendering time is highly dependent on scene complexity. As a consequence, interior designers should be very careful when choosing the right render engine.

What Is V-Ray

V-ray is a render engine, which means it adds some extra features to the existing software such as: 3D Studio Max, Maya, Blender, Rhynoceros 3D, etc. by improving the render speed and quality. This render engine aims to create photo-realistic images for the needs of the interior and exterior design, product design, and animation. This entry exams the V-ray as a plugin to 3D Studio Max and all examples are produced in 3D Studio Max. However, the Render Setup menu allows to set up the right render – Mental Ray, V-ray, or V-ray RT. The last one enables its users to utilize both CPU (central processing unit) and GPU (graphic processing unit) hardware acceleration and to see the update to the render while they edit the scene in real time (lights, materials, textures, camera, etc.).

Regarding the functionality of V-ray, this render engine provides users with its own lights and camera.

V-ray lights include a set of lights that are specially designed for application in 3D Studio Max. The standard Ray Traced Shadow and

Shadow Map shadows are optimized to work with V-ray. However, V-ray offers its users with a V-ray Light Meter Utility that enables them to evaluate the lighting in a scene and to make certain adjustments in order to refine the lighting. Depending on the effect designers want to create, they could use some of the following lights, determined by CHAOS GROUP (http://docs.chaosgroup.com):

- Area lights – V-ray light that can be used to create physically accurate area lights of different shapes. Designers could choose some of the following types of shapes: plane light, disc light, sphere light, mesh light, and dome light.
- A Sun light – designed to work together, V-ray Sun and V-ray Sky reproduce accurately the real-life Sun-Sky environment.
- Photometric lights – it enables the users to utilize *.ies files* – it is a file which contains specific features of a real-world light bulb.
- Ambient light – this light does not come from specific directions and it could be used to reproduce or simulate global illumination.

The accurate usage of the above-explained lights would allow interior designers establish a full-fledged 3D scene and enable them to customize precisely the lighting effects they intend to create.

V-Ray Physical Camera

However, a 3D photo realism could not be possible without using an appropriate camera. The camera is the tool that captures the image/s and enables the cameraman to tell stories. Knowing how to manipulate and control the camera settings will make possible to achieve all of the above-mentioned real estate photography principles and, thus, to engage deeply their clients. This entry makes a parallel between the features provided by the real camera and the one V-ray provides in 3D Studio Max.

The V-ray Physical Camera in 3D Studio Max is a powerful tool which aims to narrate a certain story through its infinite number of tools. For instance, painters use different types of compositions, colors, shapes, and forms in order to convey emotions and induce feelings. Photographers and cinematographers use compositions, point of view, exposure, and motion. These settings help the authors to create their visual language. The camera is an essential and powerful tool for all interior designers and animators which they use to visualize their projects. Taking advantage of its wide variety of settings, interior designers would be able to establish a full control of the perspective and as a consequence to enhance the quality of their final output. There are some really vital elements that need to be considered in order to obtain a better understanding of how the V-ray Physical Camera works and how its settings could be used for the needs of the interior designers.

The V-ray render engine is a complex plugin that offers an infinite number of settings enabling users enhance the realism and avoid many problems such as: noise, flickering, etc. Most of the V-ray menu options are highly dependent on each other. The researcher will explore in-depth the most important V-ray Physical Camera abilities, rather than explaining the most essential settings in a top to bottom manner. In order to establish clarity, the author's considerations are focused on the camera as an important element that has a significant contribution to the quality of the final render. Furthermore, the camera constitutes just part of a complex render algorithm which is based on the settings, provided by the main V-ray menu. This menu provides a large number of abilities that improves the rendering and its performance, such as: Global Illumination (GI), Image Sampler, Adaptive DMC, etc.

Thus, a parallel will be done between the real-world camera and the one provided by V-ray in 3D Studio Max, called V-Ray Physical Camera.

This comparison aims to identify whether the V-ray Physical Camera has the same abilities and settings that the real-world digital camera has, in order to achieve and incorporate the five principles listed above.

Many experts claim (Obeo 2017), the real-estate photography has some special requirements to the equipment, e.g., the photographers should be provided with a digital single lens reflex

camera (DSLR) body, tripod, flash, and a full gamut of lenses. V-ray in 3D Studio Max offers all of these facilities – an effective synergy between the V-ray Physical Camera, V-ray Lights, and some advance render settings. In addition, many practitioners recreate the flash effect by aligning a V-ray white-colored light with a very small amount of multiplier to the camera.

The real-world camera (DSLR or a mirrorless interchangeable lens camera) enables their users to control a number of settings, some of which are quite important for incorporating all of the above-mentioned design principles. The analysis will be based on the following control settings:

- Control the field of view
- Controlling exposure (shutter controls and aperture controls)

Field of View

The field of view is one of the most important parameters to which designers should pay attention. It illustrates what angle is captured by the lens and thus it enables the interior designers to incorporate principles: 1, 3, 6, and 7 (Lohrman 2014) in their projects:

The field of view is dependent of two main factors, explained by Douglass Kerr in his study "Equivalent Focal Length":

- The focal length – it determines the angle of view or, in other words, how much of the scene will be captured. The greater the focal length, the narrower the field of view is (Kerr 2009).
- The camera's format size – it refers to the size of the film frame or with the size of the digital sensor. In general, the smaller the format size, the smaller the field of view. Nowadays, the most popular digital single reflex cameras are manufactured with sensors nearly equal to those of 35-mm film. For example, regarding the digital photography, a lens is deemed to be a "normal lens" when its focal length is approximately equivalent to its sensor diagonal size (Kerr 2009).

In photography, there are certain types of lenses that enable photographers to capture interior scenes with different field of view. Some widely available lenses according to the standard 35-mm cameras are the following:

- Normal lens (50 mm, 85 mm). It reproduces fairly the same what the human eyes see.
- Wide-angle lens (10–42 mm). When comparing with the normal lens, it captures relatively wider angle. For instance, small-sized bathrooms, bedrooms, and cellars are difficult to shoot without having such kind of lens. Many experts and photographers claim that all real estate look better when using a wide-angle lens. The type of lens should be selected carefully in order to avoid distortion and inaccurate perspective.
- Zoom lens (100–800 mm). Nevertheless, it is rarely used for taking photos of real estate scenes – it captures relatively narrower angle, comparing with the normal lens. This lens allows the users to adjust the focus ring in order to change the focal length. This process is known as lens breathing. However, by using this lens, the photographers should be aware that they distort the depth of field (DOF).
- Depth of field – There is a plethora of terms that are tossed around DOF. However, Nagahara et al. (2008) determine the depth of field as a range of scene depths that appear focused in an image. Furthermore, the strength of DOF is highly dependable by the aperture. By successfully utilizing the DOF, the real estate photographers could emphasize certain focal point of the living space that should be in focus and visually appears as the most obvious point spotted in the interior.
- Fish-eye lens (7–16 mm) – this lens provides an immensely wide angle and it distorts the straight lines into curves. The interior photographers utilize it when it comes to creating some special effects or unconventional point of view.

A comparison between the real-world camera and the V-ray Physical Camera features, which is based on the above-mentioned characteristics, is illustrated in Table 1.

3D-Rendered Images and Their Application in the Interior Design, Table 1 Comparison between the Field of View (FOV), provided by the Real-World Camera and the V-Ray Physical Camera

Field of view	Real-world camera	V-ray Physical Camera
Depth of field	Yes	Yes (users can specify the DOF depending on the film/sensor preset chosen)
Focal length	Yes	Yes (default is 40 mm and could be customized)
The camera's format size	Yes	Yes (default is 35 mm and could be customized)
Lens breathing	Yes	Yes (default is 1.0 and could be adjusted)

Exposure Control

The most important exposure controls on your camera are the shutter speed, aperture, and ISO, because they affect the total amount of light hitting the camera sensor (Curtin 2011). These settings are also determined as an "exposure triangle," by photographer Barry O Carroll (www.bocphotography.com).

The V-ray exposure control menu (Figs. 1 and 2) allows to adjust these settings and to choose between different modes when applying the exposure control. This menu offers a number of settings which are quite essential (Table 2).

Based on this table, the comparison of the exposure control settings will be like this, illustrated in Table 3:

It is also important to note that this menu enables users to adjust the white balance – quite essential features that photographers use to remove some unrealistic colors.

The researcher illustrates below some renders produced with V-ray 3.20.03, compared with photos which are taken with real-word digital camera.

Renders

The V-ray Physical Camera productions are illustrated below.

3D-Rendered Images and Their Application in the Interior Design, Fig. 1 V-ray Physical Camera menu basic parameters. (Source: Screenshot from the interface, 3D Studio Max 2016)

In Fig. 3, there is a comparison between a photo and a V-ray-rendered image. The right part of the image is rendered with V-ray, while the left is taken by DSLR camera.

Figures 4 and 5 illustrate an interior which is rendered with V-ray Adv.3.03

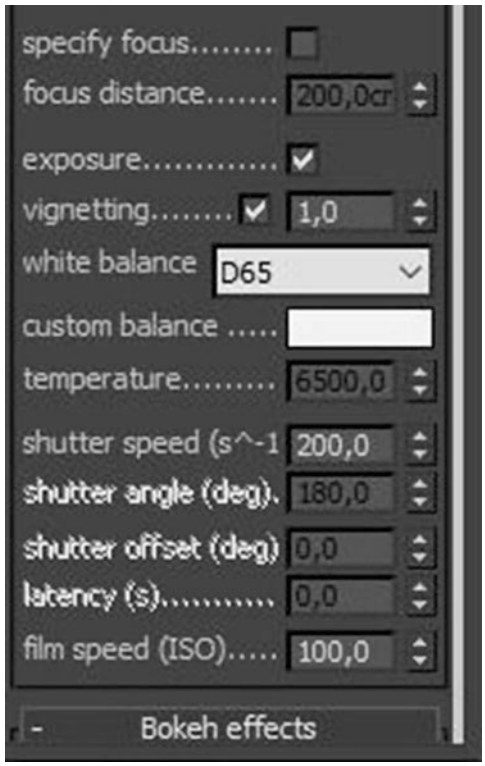
V-ray Physical Camera, ISO: 400

Shutter speed: 1/60, f 8, Vignetting – off. Lens: 50 mm.

Resolution: 6666 × 5430

The image above shows the quality of realism, produced by V-ray Physical Camera with Wide-angle lens, 28 mm and ISO 400.

All renders are produced with Vignetting: off. By enabling this setting, some dark areas appear at the image corners which could be considered from the designers as a flaw.



3D-Rendered Images and Their Application in the Interior Design, Fig. 2 V-ray Physical Camera menu (Source: Screenshot from the interface, 3D Studio Max 2016)

3D-Rendered Images and Their Application in the Interior Design, Table 2 V-ray exposure control menu

V-ray exposure control menu	
Mode	Allows to choose between different modes, e.g., photographic
Camera node	Specifies certain node from which the camera settings could be taken
Exposure value (EV)	It controls the exposure and enables to adjust the image as brighter or darker
Shutter speed	The same function as the shutter has in the digital photography. The value is illustrated on numbers, e.g. 1/200 in V-ray is 200
f-number	Controls the aperture with the same step as they are designated in the photography (1.4, 2, 2.8, 5.6, 8, 11, 16, 22)
ISO	It determines the film sensitivity. Smaller value makes the render image darker, and larger value – brighter. Unlike the digital photography, the large amount of ISO does not increase the noise in the picture

3D-Rendered Images and Their Application in the Interior Design, Table 3 Comparison between the exposure control settings provided by the Real-World Camera and the V-Ray Physical Camera

Exposure control settings	Real-world camera	V-ray Physical Camera
Shutter speed	Yes	Yes
f-number	Yes	Yes
ISO	Yes	Yes

Conclusion and Discussion

Taking into account all of the explained considerations, it is clear that CGI has a strong and essential impact on the interior designer's workflow. Today's clients have very high expectations and very short attention spans. Thus, the interior designers face a challenge to constantly improve the quality of their outcomes, by providing their consumers with top-quality projects. In order to achieve the expected results, the practitioners should optimize the time they spend to enhance their performance. Being aware of the abilities that the contemporary 3D software and its related plugins provide will significantly facilitate the relations between interior designers and their clients. The listed analysis and illustrative examples above suggest that V-ray and its camera could be successfully adopted by the professionals in order to create visually compelling, high-realistic images. V-ray Physical Camera is unable to solely achieve the desired render quality – the CGI realism is a result of complex algorithm that in general includes the accurate use of materials, lighting, camera, and some generic render settings. Nevertheless, the camera plays quite essential role when it comes to visualizing the project and the V-ray Physical Camera provides users with all abilities that the real-world camera does. However, regarding the parallel between these two elements: the virtual and the real-world one, the V-ray Physical Camera has an advantage regarding the ISO. The real-estate photographers often suffer when using

3D-Rendered Images and Their Application in the Interior Design, Fig. 3 Comparison between photo and V-ray render. (Source: Created by the author – Petyo Budakov, Ph.D. in 3D Studio Max 2016)

3D-Rendered Images and Their Application in the Interior Design, Fig. 4 Interior design, rendered with V-ray. (Source: http://help.chaosgroup.com/vray/help/rhino/200R1/images/tutorials/interior/Final%20Render%20002.png; Created by the author – Petyo Budakov, Ph.D. in 3D Studio Max 2016)

inaccurate ISO values that make their photos noisy or grainy. This problem is completely resolved by the unique V-ray algorithm which opens new horizons to achieve extremely high realism in terms of interior design projects. Furthermore, the application of the 3D-rendered images have its strong impact on the real-estate marketing – 3D models are used to promote the sale of property by providing lenders and investors with a good understanding of the project's vision. The high-realistic 3D virtual projects significantly facilitate the sales of incomplete properties by providing buyers with a clear vision and precise idea of their future homes. Obviously, the economic benefits are also present – instead of using some less attractive two-dimensional sketches, wasting time until the property is accomplished, and then hiring a photographer to take the photos, the interior designers are capable to do all this in advance. As a consequence, the project becomes much more affordable and a recently conducted survey by Real Estate in a

Digital Age (2017), 50% of the buyers find the 3D visualizations and virtual tours as a preferable option that facilitates their final decision for purchasing.

As a conclusion, the 3D-rendered images transform not only the interior design in general but also make a strong impact on the real estate marketing.

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design

Daniel N. Boulos
University of Hawai'i Manoa, Honolulu, HI, USA

Synonyms

Accord; Conform; Formalize

Stylization is at the heart of 2D animation design and is only recently being more fully explored in 3D animated films. In the early days of 3D animation, the push for realism in lighting, rendering, and deformations displaced a pursuit of stylization in the quest to expand the capabilities of computer graphics technology. With those technical problems solved, 3D animation has more recently embraced stylization in design and character movement. Stylization also can be interpreted by some as playfulness, and "play is at the heart of animation" (Powers 2012, p. 52). Nature can be seen as an "abstract visual phenomenon" (Beckman and Ezawa 2012, p. 101), and "the portrayal of hyperrealistic human characters in 3D animation can lead to the alienation of an audience, as they may not accept them as being real" (Kaba 2013, p. 188). It is the ability of animation to "break with naturalistic representation and visual realism" (Linsenmaier 2011, p. 1) that is observed as one of the strengths of the art. This entry discusses the implications of stylized design and its use in 3D animated films while drawing important references to traditional hand-drawn animation stylization processes that pose a challenge to modern 3D animation studios.

Definition

Stylization is the process of depicting or treating a subject in a nonrealistic approach according to an artistic convention. Stylization in animation includes the two- and three-dimensional graphic representations of characters and objects as well as the fourth dimension, stylization of timing, and movement.

Background

"Traditionally, computer graphics pursued the reproduction of real world. Consequently, many efforts were devoted to the photorealistic approach of rendering and processing images" (Sparavigna and Marazzato, p. 1). This observation is important as it identifies a fundamental challenge of stylization in 3D animated feature films. Animated films are most often driven by the concerns of narrative storytelling structure. Although some subject matter in narrative story may benefit from a photo-realistic approach to 3D imagery, the desired effect of many films is to remove the audience from their daily experience and provide immersion into visualizations that depart from realism. Sparavigna observes, "However, it is not obvious that a photorealistic processing is always to be preferred. . .Hand drawn illustrations can better explain a scene than photographic plates, because in illustrating complex phenomena, they can omit unnecessary details and propose only fundamental objects" (Sparavigna and Marazzato, p. 1). One benefit of a departure from photorealism is the ability to communicate effectively and efficiently. Visualization in narrative film structure provides an opportunity to reinforce story points, clarify what is taking place, and also enhance the emotional context of the screen experience for the audience.

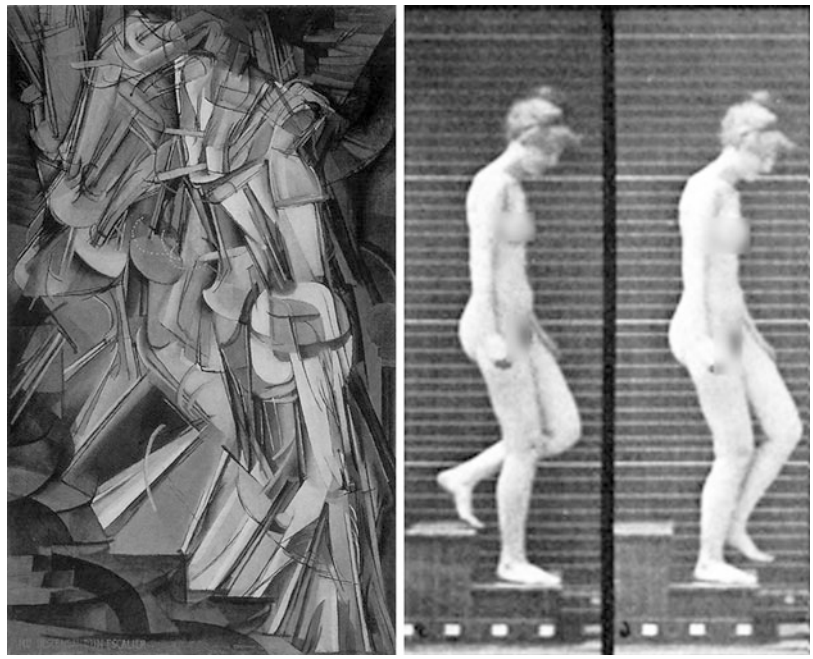
When examining the art of oil painting, where the design and construct of imagery is of equal importance, the movements of Postimpressionism and Modernism exemplify this point. The visual experience in Vincent Van Gogh's Starry Night is entirely dependent upon his unique interpretation of the observed phenomenon of the night sky. Without this process the work would lose its visual identity and much of its emotional content (Fig. 1).

In Marcel Duchamp's Nude Descending a Staircase No. 2, we observe the power of stylization in communicating motion and once again emotional context (Fig. 2).

Definition of *Style*

The *Oxford Dictionary* offers the following definition for *style*, "A distinctive appearance, typically determined by the principles according to which something is designed" (Oxford 2015). The term "distinctive" is helpful, as one benefit of stylization is a unique visual identity. The term "designed" implies the intent to implement a process leading to visual identity.

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 1 Van-Gogh's *Starry Night* to photo comparison



Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 2 Duchamp's *Nude Descending a Staircase No. 2* photo comparison

Stylization in the 2D Animation Feature Film Process

Stylization is at the heart of the animation industry. A photo-realistic design of an animal such as a bear cannot be easily registered for copyright; however, a highly stylized interpretation of a bear such as Hanna and Barbera's *Yogi Bear* is copyrightable as a creative work. Such character design copyright is at the foundation of animation merchandising. Stylized character designs are highly profitable for animation studios often generating more returns than the initial film the design appeared in.

The production process of traditional 2D animated feature films leveraged stylization at many points within the creation timeline. It was often highly stylized representations which first visualized a story idea in the *visual development* phase of preproduction. Stylization was a central part of the 2D *layout* process where line drawings for each background painting were carefully created. Following the instructions of an *art director*,

specific stylization concepts would be applied by layout artists as they would interpret the setting of the film, designing backgrounds for all shots within the film. The *supervising animators* then applied stylization, as they began the experimental animation that would set the tone for their characters' performances. The final design of the character was informed by the stylistic theme of the film. In these images from Walt Disney's 1959 feature *Sleeping Beauty*, it is evident that stylistic choices created for the background design in a shot flowed into the interpretation of line and form in the character design (Fig. 3).

The architectonic styling of the gothic-inspired backgrounds by stylist Eyvind Earle carry through into the angular interpretation of the characters; a harmony is achieved between the stylization applied to the props, set elements, and the characters.

However, the stylization process did not end with the look and feel of the character designs, backgrounds, and props. Stylization was central to movement in character animation; the animation of the characters themselves provided a richly stylized experience of real-world motion and timing, much in the same way a ballerina stylizes such mundane activities as walking or such unreal activities as flying like a swan.

Finally stylization was also applied in the interpretation of natural phenomenon. This example from Walt Disney's *Hercules* shows a stylized approach to the effect of a smoke cloud. The representation favors specific types of curvilinear treatments and angular oppositions. The visual interpretation stands in marked contrast to the same event in the physical world (Fig. 4).

Realism in Early Computer Graphics

The value of computer-generated imagery as a visual effects element for live-action film was evident from its early use such as in the 1973 film *Westworld* and the 1977 film *Star Wars Episode IV*. Throughout the 1980s computer graphics played an ever-increasing role in live-action visual effects. Animation that had traditionally been accomplished through stop-motion techniques was soon replaced by 3D computer animated effects. Accordingly, 3D animation tools evolved along a trajectory of photorealism. Lifelike portrayals of light and shadow as well as color were necessary for seamless compositing with live-action elements. The need for realistic treatments influenced the evolutionary path of 3D technology during the same period when uses for 3D graphics and animation were still being defined. After Pixar's great achievement and critical success with *Toy Story* in 1994, it was established that 3D animation could compose the entirety of a film. Rather than a means to an end, as in the case of visual effects, 3D animation had become a final product. It would take however

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 3 Design examples from Walt Disney Pictures' *Sleeping Beauty*

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 4 Walt Disney Pictures' *Hercules* to photo smoke comparison

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 5 Example of thick ink lines from early television animation (1950s)

several years to break from the pursuit of realism and implement stylization on a broad scale.

The Influence of Technology

Early Television

Early television broadcasts were of limited resolution with two alternating fields of horizontal lines creating each final frame. The thin lines of hand-inked animation cells used in theatrical shorts did not display well, and at certain tangents to the horizontal could be lost altogether during broadcast. The use of thick ink lines in television animation produced a solution that was not only functional but also a stylistic standard for the new medium (Fig. 5).

Early Internet

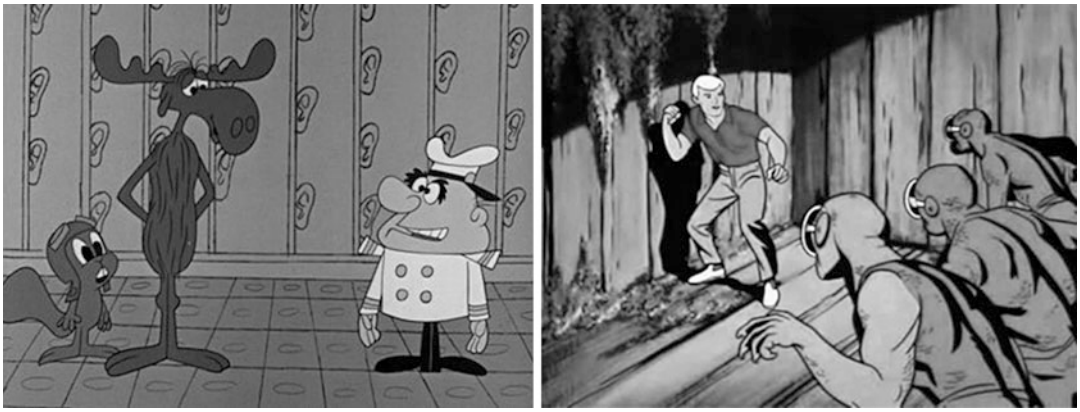
Early web animation utilized Flash software and introduced the use of stylized thick ink lines to vector animation. Flash vector animation populated the web of the 1990s offering motion graphics via the low-bandwidth Internet connection common for that time. Flash software was adapted for television production as it offered timesaving advantages previously impossible in the limited animation repertoire. The characteristic use of line and shape from early web animations found its way into many television shows of the last decade. A clear visual parallel can be seen in the flat graphic character styling favored by early television animation of the 1950s and the Flash-influenced television designs of the last 15 years (Fig. 6).

Filmmaking

Stylization and Genre

Stylizations themselves can be seen to splinter through the prism of genre. For example, the

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 6 Examples of Flash television animation styling (2000s)



Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 7 Example – genre stylistic differences in early television animation

stylistic conventions in *Rocky & Bullwinkle* contrast against the variations seen in *Johnny Quest*, which was influenced by comic book illustration (Fig. 7).

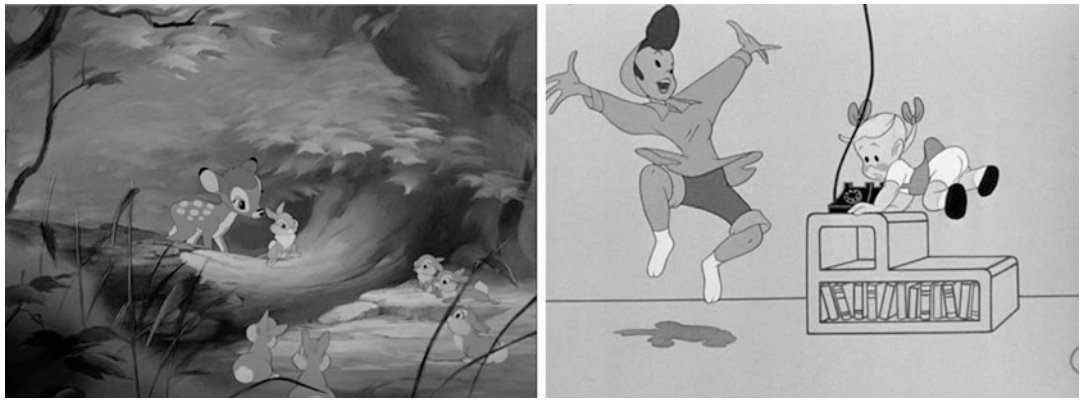
Early Disney theatrical features, such as Bambi, can be seen in stylistic contrast to musically derived works such as *Fantasia* (1940) or *Make Mine Music* (1946). In *Bambi* the soft-edged painted treatments by stylist Tyrus Wong set the mood and look of the forest in which the highly stylized design of the character Bambi, from animator Marc Davis, performed. In *Make Mine Music* minimalized character and background treatments in the segment *All the Cats Join In* were a significant departure from more detailed human characters in the narrative plot-driven features (Fig. 8).

The music-driven films were segmented into separate capsules more indicative of the animated short format. Narrative-driven features had the burden of clarifying complex character arcs, staying onscreen for extended periods. More detailed facial treatments were dictated by these genre-induced requirements (Fig. 9).

For example, the white region of the eye is important in subtle facial expressions, and a more stylized treatment of an eye may not encompass the same expressive range.

The Role of Stylization in Storytelling

Stylization plays an important role in narrative story telling as seen in such early live-action films as Murnau's 1922 *Nosferatu* where the stylized uses of shadow and form set an eerie context or in animated sequences such as the stag fight



Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 8 Background and character comparison of *Bambi* and *Make Mine Music*

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 9 Facial detail stylization – comparison of *Bambi* and *Make Mine Music*

near the end of the theatrical feature *Bambi* where the stylistic treatments of color and form enhance the emotional drama of the battle (Fig. 10).

Design Principles and Screen Composition

Stylization is born of visual design principles and gains effect from their successful implementation. The elements of visual design are the tools of the stylist as they interpret objective visual facts, into their final subjective states. *Shape*, *form*, *color*, *line, texture*, etc. are manipulated in tangible ways, employing design concepts such as *theme and variation* and *contrast* and *harmony* while enhancing rather than reducing a film's context.

Students in art programs are taught, as foundation, the importance of design principles and their corresponding emotional impact on the viewer. Often through slight changes in the alignment of forms in a visual field is *balance* achieved or such subtle linking through *contour continuation* fully realized. In their early years Walt Disney Studios was particularly sensitive to the relationship art had to animation and endured great effort and expense to expose its employees to these concepts via art classes and seminars. Transcripts from the 1930s recorded artists in such evening seminars isolating what are now taught as *animation principles* (Johnston and Thomas 1984, pp. 71–72).

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Fig. 10 Stylization examples from *Nosferatu* and *Bambi*

Trained artists filled the majority of positions in 2D animated production pipelines. The effect of this foundational integration of artists in the animation process led to the formation of visual identities within animation studios, often around a handful of celebrated stylists. Maurice Noble had a profound impact on what came widely recognizable as the "look" of a Warner Bros. animated short. Similarly Mary Blair impacted the look of Disney features and short subjects through multiple stylistic interpretations as can be seen in *Saludos Amigos* (1942), *Johnny Appleseed* (1948), and *Peter Pan* (1953), three works that demonstrate a wide range of visual interpretations.

Character Animation: Stylized Timing in 3D Features

Stylization in movement is the realm of the character animator. There have been notable achievements and a new emphasis now placed on stylization in 3D character animation.

The Emergence of Stylization in 3D Character Animation

Many efforts were made toward stylization in the early history of 3D feature film production. Some labors were rewarded more than others; however, it can be clearly seen by the time of the Pixar film *The Incredibles* (2004); the final technical hurdles had been overcome and stylization began to enter with greater impact. Not only did this film achieve significant stylization in character design but notably in character movement as well. The clarity and exaggeration of animation poses became comparable to 2D animation. A break from realism is at the center of the appeal of Mrs. Incredible whose body stretches to outrageous lengths in the hallway sequence as she tries to find her husband. A comprehensive stylistic aesthetic carried over from development art into prop design, set elements, and lighting.

Stylized character movement began to appear more consistently outside of Disney/Pixar films, as is exemplified by the Sheriff Earl character in Sony Animation Studios' film *Cloudy with a Chance of Meatballs* (2009), as the sheriff bounces and flips rather than walks through a crowd. It was clear that 3D animation directors were embracing nonliteral forms of movement. The trend continued in *Cloudy with a Chance of Meatballs II* where the fraudulent guru, Chester, twists, slides, and gyrates from pose to pose, devoid of literal movement that could have originated with motion capture technology or other automated methods. The 2010 release *Tangled* from Walt Disney Pictures stood in contrast to character movement in early 3D animation efforts as it exhibited the strong clear poses and simplified exaggerated movements that had been indicative of high-quality 2D character animation. Finally, Walt Disney Pictures' *Wreck-It Ralph* (2012) is full of stylistic motion intended to mimic the movement of pixel-graphic video games. Characters move in multiple styles within single shots. One character may be devoid of animation principles such as Arcs resulting in stiff and unnatural movement, while the next character may follow the standard principles of movement resulting in a natural screen presence. 3D character animation success stories such as these contrast with automated processes such as *motion capture*. Motion capture is a process that conceives 3D character animation as a copy of real-world movement, while keyframed 3D character animation builds on a foundation of 2D character animation traditions such as *exaggeration* or *simplification*. Automated processes negate the interpretive role of the animator as stylist, resulting in movements that are prepared rather than designed.

The Influence of 2D Animators on the 3D Pipeline

These 3D stylistic trends can be associated with the arrival of many traditional 2D animation artists who have joined the ranks of 3D studios. Many animation artists were displaced by the closure of 2D feature animation production at Disney Studios in 2005 (Forum.rottentomatoes.com 2005), as well as DreamWorks and Warner Bros. The resulting talent migrations had an impact on several 3D animated feature productions.

In the case of *The Incredibles*, it was the first full 3D feature animation effort for director Brad Bird who had been brought to Pixar by John Lasseter. *The Incredibles* production saw the arrival of animation director Tony Fucile who had been a supervising animator on the 2D film *The Lion King* before working as animation supervisor under Brad Bird on the mixed 2D-3D features at Warner Bros. In the case of *Cloudy with a Chance of Meatballs*, Sony Pictures had been on a course of introducing 2D talent within their 3D ranks as Roger Allers and Jill Culton, codirectors for *Open Season* (2006), and Chris Buck and Ash Brannon, codirectors for *Surf's Up* (2007), all had their roots in 2D feature animation. Finally codirectors Jim Reardon and Rich Moore *(Wreck-It Ralph, 2012)* were graduates of the Character Animation Department at CalArts and also had their roots in 2D animation techniques.

Challenges in the 3D Feature Film Pipeline

There is no one-size-fits-all approach to stylization nor should there be in the quest for visual identity among the scores of animated features released each year. Although stylization is widely addressed in 3D animated features today, often it is not fully realized particularly in scene design and screen composition, leaving many 3D features with a similar look, lacking visual appeal.

Stylization is a key ingredient in film, affecting qualitatively the dialog with the audience and enhancing the narrative. It should be fully implemented in animated film, where it is most readily available. It is unfortunate to see many 3D animated feature films offer little stylization and routinely forgo the advantages that stylization brings. This phenomenon can be examined from several perspectives, but here it is seen through a close look at the 3D pipeline and the hundreds of workers that create the final films.

Compartmentalization: Disintegration of the Design Process

As was explored earlier the 2D animated feature film pipeline relegated the bulk of stylistic control to relatively few artists. All of it was found in preproduction or early in the production phase of the film. The art director and key development artists along with supervising animators and the layout department determined the bulk of stylistic integration before the majority of the people involved in production would begin their work. In their early and concentrated efforts, most consequential decisions were made determining the final use of color, form, and directionality in screen composition.

However, the 3D pipeline presents a more complex and compartmentalized process. Although most 3D feature films have the benefit of both development artists and art directors, the difficulty is in the component processes collectively resulting in the final color and composition of each shot. The work of the 3D development artist gives way to the modeling artist who first visualizes the characters, props, and set elements in 3D geometry. The texture artist further contributes in ways that directly impact stylization. The composition of the scene falls to a set decorator or shot composer then continues on to layout artists who block in the camera movement affecting each scene's composition. The animator follows with the keyframing of character elements, working primarily in the roughhewn visual context of low-polygon models. In a subsequent step further animation is added through automated simulations and dynamic options and processes. Final lighting is then applied to the scene, only beginning to address the integral role of shadow and light in screen composition, at a very late stage in the process. It is when each frame is finally rendered that the shot design and composition arrive at their final state.

Implementation of stylization in the 3D pipeline involves many departments, beginning early in preproduction and ending with final render. By comparison the 2D stylization process was in the hands of few artists, heavily weighted toward the preproduction phase of the film process. The length and complexity of the production of the 3D imagery as it moves from concept to completion poses many challenges to stylization in 3D film. Even with the efforts of a dedicated production stylist, visual influence is diluted as stage by stage a single shot is completed over a long period of time.

Demographics of the Production Team

The evolution of computer-generated technology was so strenuously focused on photo-realistic achievement for such a long period that stylization developed little momentum, often weakly integrated or entirely absent. As 3D animated features quickly supplanted the 2D animated format, the balance of production personnel changed in a dramatic way. In the typical 2D animated feature film, more than 80 % of the preproduction and production team came from an art background. The 2D production team required 300–500 people most of whom had to be able to paint or draw well. As a result most crewmembers had attended art programs within universities or colleges before contributing to the film. By contrast 3D animated films require a more diverse range of skills. Computer technology is central to all the elements in each shot of a 3D film. As a result technologists are as numerous as artists on many 3D features. While a 3D character animator will graduate from an art program, a character technical director will graduate from a computer science background. The table below clarifies the proportional difference between the two respective production teams. The example compares individuals listed in both the *visual effects* and *animation* categories in the film credits for *Inside Out* (2015), the 3D example, and *The Little Mermaid* (1989), the 2D example (Table 1). The crew totals for each film are much higher; the sample was limited to the personnel involved in the production process for the two listed categories. It should be understood that the 43 people in the technical processes for 2D animation would have contributed most of their efforts in postproduction after the hands of the 307 artists have already touched the film.

The 3D film process is challenged by this change in balance, as the production team moves away from a common background in art to one pulling heavily toward digital technology. Thus,

Abstraction and Stylized Design in 3D Animated Films: Extrapolation of 2D Animation Design, Table 1 Demographic shift in the constituency of feature animation production units (Data retrieved from IMDB.com)

Inside Out (2015a) *3D animation*	**The Little Mermaid** (2015b) *2D animation*
Animator or character designer: **25**	Animator, painter, character design, layout, 2D effects: **307**
Software, simulation or technical: **17**	Xerographic or technical: **43**
Percentage of sample that are artists: 59 %	**Percentage of sample that are artists: 87 %**

the largely artistic process of stylization has not only been spread across a much broader span of production time but among a different set of contributors. Without a common artistic background rooted in design principles and aesthetics, the understanding of stylization and what constitutes successful implementation may be a point of conflict within 3D production teams.

Conclusion

The Need for Visual Identity

Animated feature films are more abundant today than at any other time in the history of film. The vast majority of these films are 3D animated features.

Restructuring the 3D Pipeline

It may be advisable to revisit the 3D pipeline in an effort to identify alternate methods for gaining the control necessary for significant and successful stylization. There must be an effort to simplify the pipeline or further empower the art director over component parts of the process. It may be that one art director alone will not be able to track the myriad simultaneous decisions, which are the standard for efficient 3D production. Perhaps there will be room to experiment with the art director as a team or creative unit rather than a sole individual. This team could be as many as 20 or more persons; thereby, an art director for the team would be able to monitor each shot through every stage of the pipeline.

It is further advisable that other methods such as the stop-motion animation pipeline be examined as possible influences for change. Perhaps one day final lighting and texturing will precede character animation in much the same way shaded layout drawings set the stage before the 2D animator ever set pencil to paper. As many times as the 3D pipeline is repeated, it ought to be reimagined; such a young set of processes should be ripe with experimentation. These experiments should be guided by design principles and stylization ideals, which ultimately trump technology as a film seeks its emotional connection with the audience.

Education and Training

It would be equally advisable to educate 3D production teams in artistic processes in an aggressive and meaningful way, with a desire to learn how such processes were employed in 2D animation units. Educating the team and developing a common core design philosophy would help assure that stylization goals are met at all stages of production.

It is very hopeful that stylization will be fully realized in the future of 3D animated films, as the existing tools and processes are capable of far greater results in this quest.

Academic and Video Game Industry "Divide"

Jordan Greenwood and Grant Meredith
Federation University, Mt Helen, VIC, Australia

Synonyms

Divide; Gap; Rigor-relevance debate

Definition

The "divide" can be classified as the limited transference and dissemination of knowledge, and the lack of collaborative projects between academics and their industrial counterparts. The extent to which the divide exists between the games industry and academia lacks clarity and needs continued research.

Introduction

Contemporary game design and development has been impaired by poor communication between related practitioners and academics (Passarelli et al. 2018; Greenwood et al. 2021). In academia, game design is contextualized within the study of games, the act of playing them, and the cultures surrounding them (Engström 2020). In contrast, at the industry level, the focus on game design has revolved around self-expression, overcoming challenges, player experiences, and making a profit (Davis and Lang 2012). The reasons for poor communication between both parties are complex, focusing on the importance of creativity and business management, and therefore attention is mostly given to game mechanics, aesthetics, and marketing strategies (Marchand and Hennig-Thurau 2013). These differences in priorities and resulting mismatch of understanding are known as the "academic-industry divide" (Colusso et al. 2017).

To further understand the *divide*, it must be understood clearly that academics and practitioners have differing motivations driving how they approach the gaming discipline. Typically, academics focus their research on how games generate social and cultural meanings, and how game mechanics and aesthetics can inform the development of new games (Engström 2020). Whereas industry practitioners focus their attention on providing immersive experiences for players and ensuring a profitable outcome for themselves (Davis and Lang 2012). A result of these differing motivations is that academics and industry practitioners often think that they are discussing the intricacies of the same situation/s, when in fact they are not, due to not understanding the importance and links between their related work.

How the Divide Is Appearing Within the Gaming Industry

Beginning in 2016, the European Commission–funded project, *Gaming Horizons* (www.gaminghorizons.eu), investigated video games

and society from a social sciences perspective (Passarelli et al. 2018, 2020). This study found that there was a clear working divide between gaming practitioners and academics. Extending on Passarelli and colleagues, Engström (2020) suggested that the divide needs to be viewed from different perspectives before a proper assessment can be made about the extent to which it exists between the games industry and academia.

Viewpoints on the Divide

There are two opposing viewpoints concerning the general academic-industry divide: the proponents for bridging the divide and those who believe that it should not be bridged.

The divide should be bridged: The ideal is that by working with industry, academics can engage in joint sensemaking to generate new and useful knowledge that can be used to improve processes and products (Shani and Coghlan 2014).

The divide should not be bridged: Based on Luhmann's (1995) system theory which outlines the extreme difficulty in integrating knowledge that has been generated in different contexts of science and practice (Kieser and Leiner 2012).

Benefits of Bridging the Divide

Within differing disciplines, studies into bridging the academic-industry divide have identified more barriers than benefits. This could be because those studies were limited to identifying barriers of the divide or were more focused on why the divide exists and not on the outcomes of successful bridging attempts (Beck and Ekbia 2018). The benefits for bridging the divide can be summed up as follows:

The benefits for academics: access to current industry knowledge, data, and practices; employment for graduates; and opportunities to innovate and to access alternative funding streams from governments or industry bodies.

The benefits for industry: access to additional avenues to solve problems; access to skilled employees; and opportunities to work on alternative projects of commercial value and access to recognized world experts within defined areas.

Barriers of the Divide

On the contrary, previous research into the divide within other disciplines has identified many barriers. These barriers of the division are categorized into three main groups: communication, knowledge transfer, and collaboration outlined below:

Communication barriers: The accessibility of research outside of academia and industry's ability to access and understand it.

Knowledge transfer barriers: Relevance issues and academics viewed as being poor at communicating their projects outside of the academic field.

Collaboration barriers: Funding and management issues; issues over project intellectual property, and perceived trust issues between the two communities.

Suggestions on How to Bridge the Divide

To assist with bridging the divide, suggestions have been offered. The suggestions have been categorized into three main groups: general, collaboration enhancement, and knowledge transference outlined below:

General suggestions: Such as the development of different documents for different audiences and using the agile research network approach.

Collaboration enhancement suggestions: Such as academics need to learn about industry practices and industry needs to learn about what academics are doing.

Knowledge transference suggestions: Such as academics developing libraries and translational resources and the development of an online space to communicate.

It must be highlighted that most of the suggestions made to reduce the divide have not been

implemented into practice or if they have, they have not been as successful as one would hope (Norman 2010).

Communities of Practice

Research that studies communities of practice have also shown that academia and industry have different core goals, views, and agendas (Gray et al. 2014; Wallin et al. 2014; Colusso et al. 2017). This has led researchers to show them as two different sets of communities. For example, academia's goal is to seek and generate knowledge and to provide training for future careers, whereas industry is focused on building products and the selling of goods to make a profit (Lameman et al. 2010; Wallin et al. 2014). The question now is whether the two communities can interact without support, or if it is better to develop an ecosystem that supports communication between the two communities.

At the 2021 Interactive Games and Entertainment Association (IGEA) Education Summit, a panel discussed the forming of a community of practice within the Australian and New Zealand population. The panel also attempted to prompt the values of academics and practitioners working together to improve the education of future members of the game development community, which is a good starting point for future discussions (IGEA 2021).

With this knowledge will Australian and New Zealand universities and video game practitioners take up the torch that the IGEA are proposing, to start forming collaborations such as developing programs like the Mighty Kingdom Graduate Program (IGEA 2021) or the Dc Labs Institute (Ingram et al. 2020). Only time will tell where this revolution will lead.

Accessibility of Virtual Reality for Persons with Disabilities

John Quarles
Department of Computer Science, University of Texas at San Antonio, San Antonio, TX, USA

Synonyms

Accessibility; Games; Rehabilitation; Virtual reality

Definition

Immersive virtual reality – i.e., completely blocking out the real world through a virtual reality display – is not currently universally usable or accessible to many persons with disabilities, such as persons with balance impairments.

Introduction

Virtual reality (VR) has traditionally been too expensive for the consumer market, which has constrained its applicability to high cost applications, such as soldier training, surgical training, and psychological therapy. However, with the decreasing costs of head mounted displays (HMD) and real-time tracking hardware, VR may soon be in homes all over the world. For example, HMDs such as the Oculus Rift (https://www.oculus.com/) for VR and Microsoft's upcoming Hololens (https://www.microsoft.com/microsoft-hololens/) for augmented reality (AR) will change the way that users play games and experience the surrounding real world, respectively. Moreover, VR and AR can now be effectively enabled through smartphones at an even lower cost with the simple addition of a head mounted case, such as MergeVR's headset (http://www.mergevr.com/). That is, everyone with a smartphone has virtual environment (VE) devices in their pockets right now. Thus, VR will be available to consumers who may

have disabilities. However, there is minimal research that highlights the special needs of these diverse populations with respect to immersive VR. Thus, there is a significant amount of research that must be conducted to make VR accessible to persons with disabilities. This entry reviews the recent efforts of the San Antonio Virtual Environments (SAVE) lab to better understand how persons with disabilities are affected by VR accessibility.

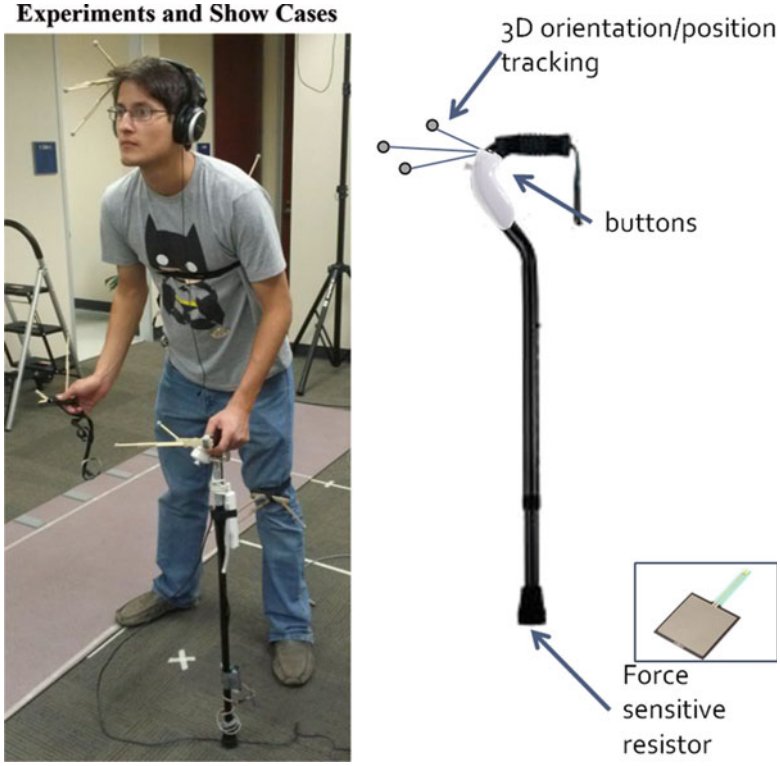
Background

Most of the information that is known about the accessibility of VR for persons with disabilities comes from research on virtual rehabilitation. VR has been shown to have significant benefits to rehabilitation. A VE is not subject to the dangers and limitations of the real world (Boian et al. 2002; Burdea 2003; Wood et al. 2003; Merians et al. 2006), which expands the types of exercises that patients can practice, while still having fun in the case of VR games. In general, research suggests that VR and VR games have measurable benefits for rehabilitation effectiveness (Sveistrup 2004; Eng et al. 2007; Ma et al. 2007; Crosbie et al. 2008; Adamovich et al. 2009) and motivation (Betker et al. 2007; Verdonck and Ryan 2008).

Visual Feedback: Visual feedback is any kind of feedback for rehabilitation delivered to the patient through the visual modality. This includes mirrors, computer displays, and VR. Visual feedback has been shown to be effective in rehabilitation (Sütbeyaz et al. 2007; Čakrt et al. 2010; Thikey et al. 2011).

Gait Rehabilitation: Gait (i.e., walking patterns) rehabilitation is the main type of rehabilitation that requires navigation in a VE. Most systems used a head mounted display (HMD) or a large LCD screen. Results with VR systems in gait rehabilitation were positive (Fung et al. 2006; Tierney et al. 2007; Bardack et al. 2010).

Design Guidelines for VR Rehabilitation Games: There has been much research on deriving



Accessibility of Virtual Reality for Persons with Disabilities, Fig. 1 Game Cane. The user leans forward to move the character forward and rotate the cane to steer. If more weight is put on the cane (as measured by the force sensitive resistor), it will disrupt the movement of the character in the game

design guidelines for VR rehabilitation games based on results of empirical studies (Flynn et al. 2008). Alankus et al.'s guidelines include: simple games should support multiple methods of user input, calibrate through example motions, ensure that users' motions cover their full range, detect compensatory motion, and let therapists determine difficulty (Alankus et al. 2010). There have been many other guidelines derived (Goude et al. 2007; Broeren et al. 2008; Burke et al. 2009a, b) and there is a need for more focused game design research and development for specific populations (Flores et al. 2008).

SAVE Lab's Research in Immersive VR Accessibility

Making Balance Games More Accessible

Many existing balance based games are not accessible for many persons with balance impairments. To address this issue Cantu et al. developed a novel interface – Game Cane (Fig. 1) (Cantu et al. 2014). Game Cane enables the user to control games and play balance based games using the natural affordances of a cane. The Game Cane project has two goals: (1) make balance games more accessible and (2) help users with balance impairments to improve their balance.

Specifically, users control orientation through rotating the cane and leaning in each direction to control direction of movement. To meet the rehabilitation goal of reducing dependency on the cane, putting weight on the cane will disrupt movement (e.g., make a character run slower; make a car more difficult to turn).

Results of a user study suggest that the Game Cane is easy to use and serves as sufficient motivation to depend less on the cane during game play. In the future, we plan to study long term effects of balance improvement using Game Cane.

Latency

One of the major potential threats to accessibility is latency. Latency is the time it takes between a user moving and the movement being shown on a virtual reality display (e.g., a head mounted display, a 3D projector). All VR systems have latency in them and classically latency has been the enemy of VR, often significantly hindering user performance.

However, we hypothesized that in some cases, extra latency can potentially be used for the user's benefit in areas such as stroke rehabilitation. For example, in a recent study (Samaraweera et al. 2015), we intentionally applied an extra 200 ms of latency to the user's virtual body, but only half of the body, which made the unaffected half of the user's body try to compensate for the latent half. In this study, participants were asked to walk towards a virtual mirror in which they could see their avatar (Fig. 2). Interestingly, participants did not perceive the latency effect. Based on her

Accessibility of Virtual Reality for Persons with Disabilities, Fig. 2 Benefits of Latency: a look into a virtual mirror where the avatar has 200 ms latency applied to one side of the body

promising results, we are now conducting a study on the benefits of this one-sided latency for stroke patients who commonly have increased weakness on one side. The ultimate goal is to apply her technique to help rehabilitate asymmetric walking patterns in these patients.

Accessibility for Children with Autism

Motivation may be a factor in the accessibility of 3D User Interfaces for children with Autism. It has been shown that many children with Autism have very specific and individualized interests, many of which may be uncommon. To more effectively motivate children with Autism to practice hand-eye coordination tasks, we created a virtual soccer game, Imagination Soccer (Fig. 3), where the user played the role of a goalie and he/she could customize a virtual human kicker (Mei et al. 2015). We compared customizable versus noncustomizable virtual humans. As expected, we found that the participants preferred the customizable virtual humans. Surprisingly, the users also exhibited significantly improved task performance with the customizable virtual humans. This suggests that customization is a plausible way to make interfaces more accessible for children with Autism.

Raising Awareness About Persons with Disabilities

Virtual reality still has a long way to go before it can be considered accessible for persons with disabilities. To educate future VR designers and engineers about accessibility in VR, it is important to raise awareness about the needs of persons with disabilities. One of the ways that the SAVE lab has been raising awareness is through our Virtual Reality Walk MS (SAVELab 2015b) (Fig. 4) and our Virtual Reality Walk for Autism (SAVELab 2015a). Using Unity3D (unity3d.com) and Exitgames Photon (exitgames.com) for networking, the VR walks mimic the real fundraising walks that occur annually, effectively involving potential participants who may not be able to attend the real walk. The VR walks are run concurrently with the real walks. Users can choose an avatar and virtually walk around a virtual AT&T center. Users who are remote are also able to communicate with people at the real walk since the software runs on mobile phones. However, there are still many research problems to be solved to make communication more natural and the interface more transparent. This is an area where new advances in augmented reality technology may help to address these issues.

Accessibility of Virtual Reality for Persons with Disabilities, Fig. 3 Imagination Soccer – a game for training hand-eye coordination for children with Autism

Accessibility of Virtual Reality for Persons with Disabilities, Fig. 4 Virtual Reality Walk MS – a mobile, multiplayer virtual environment for raising awareness about multiple sclerosis

Conclusion

The SAVE lab is trying to push the boundaries of VR to make it accessible for all users, including persons with disabilities. We have conducted fundamental research towards understanding how persons with disabilities interact with VR and have identified techniques to make VR more accessible. However, there is still a significant amount of research to be done before immersive VR can truly be accessible to everyone.

Adaptive Music

Shlomo Dubnov
Department of Music and Computer Science and Engineering, University of California San Diego, San Diego, CA, USA

Synonyms

Algorithmic composition; Dynamic music; Generative music; Interactive music; Nonlinear music composition; Organic music; Procedural music; Video game music middleware

Definition

Adaptive Music refers to a computer entertainment system for dynamically composing a music soundtrack in response to dynamic and unpredictable actions and events happening in a video game. Since its inception, the concept has evolved into a general approach to composition that takes into account the possibility of changing the musical material during gameplay, sometimes termed "composing for opportunities." The underlying principle is that music in a game could be initiated, triggered, mixed, or completely generated by directing the system in a way that is aesthetically appropriate and natural to the game and the user's actions. The common architecture of such a system comprises a database of musical segments or clips containing one or more musical sequences that could be launched in response to the game logic and looped as long as the scene is playing. Additional clips could be added or mixed or subtracted/muted to change the overall contents of the music. Special treatment is done to enable smooth transitions between clips, as well as adding short musical or sound elements, often called stingers, that might be triggered in response to user actions or facilitated switching music in the case of transitions by inserting music for ending or starting a musical segment. In some cases, musical algorithms can be deployed to generate the music materials directly by sending note or

musical playing instructions to a synthesis engine. Technically this requires to have a synthesizer or virtual music instrument available in the game engine to produce the sounds, which is in addition to the more common use of an adaptive playback and mixer of prerecorded music segments stored as audio files.

Adaptive Composition Methods

The main two common methods for adaptive music are horizontal resequencing and vertical layering or remixing (Sweet 2014). The names imply operations performed by a game sound system on pre-recorded musical materials that are arranged in a traditional multitrack view, where time is represented horizontally, and the different musical tracks are lined up horizontally. According to such arrangement, each vertical juxtaposition of musical tracks corresponds to a valid musical combination of simultaneous music materials, often arranged according to the different musical instruments performing the music.

The adaptive operations correspond to skipping forward or backward in time and muting or changing the relative volume/balance of musical playback between tracks. Since in practice the skips cannot be done between random time-points in a track, the music is segmented or arranged ahead of time into fixed clips that can be repeated or looped, or can be smoothly switched to different clips, with transitions happening only between ending and starting points of the clips. Accordingly, in some modern software, the geometrical arrangement of musical data is flipped so that the different clips are stacked vertically, with each horizontal arrangement corresponding to a specific scene or level in the game, with tracks containing concurrent clips arranged horizontally. Such grid/spreadsheet-like data arrangement creates a correspondence between game scenes or game levels and the musical data arrangement, where changes in game scenes or levels correspond to moving up or down on the musical data grid.

Special treatment is given to transitions, where switching between clips is done on the musical beat, so that the rhythmical structure of the music will not be interrupted. In cases where such matching is not possible, other transition methods are used, such as inserting fixed music segments that either create an ending of the previous music and starting of new materials, or create a gradual change, such as speeding or slowing down to match the tempo difference from the source (current) to the target (next) clip. Since such transition clips are not played in a loop, they are often treated as stingers, or singularly triggered musical events. Methods for automatically determining valid transitions between points in pre-recorded music requires analysis of the audio for repetitions by extraction of musical features. Research on automatic transitions detection is discussed in the algorithmic composition section.

Music Versus Sound Effects

A distinction between music and sound effects was traditionally evident as music would be produced by musical instruments and composed in some well-established musical style. Sound effects or so-called Foley effects, named after Jack Foley, were designed to create sounds that correspond to physical events that are nonmusical in their nature and largely correspond to sounds made by objects present in the game. Since the sound engines already in the early game consoles allowed both synthesis of simple tones and playback of short recordings, the same system was used to trigger sound effects and music. Historically, the earliest sounds in pinball machines were produced by physical devices, such as solenoids hitting bells, which could be all classified as sound effects. Music playback was often made available in the early game arcades, but mostly in order to register the games as jukeboxes rather than gambling machines that were illegal (Beep 2016). As the availability of both music generation and playback of sound effects was historically present in sound games, the combination of both types of sounds became part of the sound palette available to music game composers, blending composition and sound design into one common compositional strategy. In

parallel, experimental musical practices that were unrelated to video games have been explored, since the end of nineteenth and beginning of twentieth century, the possibilities for including nonmusical sounds in musical compositions. With experimental musical genres moving to mainstream in classical and pop music, game composers today blend traditional instruments with sound effect as part of their video game music and soundtrack design.

Music Role in Video Game

A common distinction is between Diegetic and Non-Diegetic Music, a term common in film music as well. Diegetic audio refers to sound that originates in the game events themselves, which could be either sound effects related to physical events happening in the game, or music that originates from a game scene, such as musical band or radio present in the scene. Non-Diegetic or extra-diegetic music refers to composed music that accompanies the scene, usually to establish atmosphere or identify a character or situation. A simple criterion to distinguish between Diegetic and Non-Diegetic Music is whether a character in the game would have heard that music or sound. Another technical difference between Diegetic and Non-Diegetic music is that the first one is usually localized and treated in the game using 3D audio engine, while Non-Diegetic music is rendered stereo, also called 2D audio. Among the roles of Non-Diegetic music, aspects of emotional subtext, intensifying the game narrative, informing about progress or level of gameplay, are often mentioned. Both Diegetic and Non-Diegetic music are important for providing a sense of immersion in the game.

Logic of Music Triggering and Combinations

One of the distinctive features in Adaptive Music is that the arrangement of musical material has to provide multiple alternative combinations of musical materials rather than creating a single timeline of musical events. Accordingly, the term nonlinear composition is often used to describe the branching structure of musical materials in contrast to a traditional single sequential arrangement of a linear musical form. This creates a novel approach to planning a composition by creating a database of sounds and identifying one or more musical sequences to have one or more decision points. The decision points within the database then comprise a composing decision tree, with the decision points marking places where branches in the performance of the musical sequences may occur. A sound driver interprets each decision point within musical sequences depending on the unpredicted actions and events initiated by a directing system that is linked to events in the game. The directing system may also query the state of the sound driver to adjust the branching decisions, such as preventing too many loops of playing the same musical material if the game activities do not progress at sufficient pace, or initiating some branching or transitions randomly, unrelated to the actions of the game, in order to create more variety in the music. Other direct commands may be initiated by the directing system for controlling the performance of the sound driver or playback device, such as adding or removing (mixing) multiple simultaneous sounds synchronously or asynchronously with another playing clip. The synchronous versus asynchronous combination is designated according to delaying playback of new sounds in order to match the rhythmic or beat structure between musical materials or triggering the new sound at will, respectively, as well as including additional decisions about the fade settings, pickup or count-in beats, or criteria for selection of the target sounds. The design of the branching logic allows for both horizontal resequencing and vertical layering composition techniques to be implemented by creating a hierarchical or coarse-to-fine tree structure with main branches corresponding to transitions between collections of sounds arranged into themes, and fine grained decisions for track selection and combination

controlled by game levels within a theme. The details of logic handling are different across different systems. For example, in the Elias adaptive music system requests to change level, use an action preset, play a stinger, etc., react differently for each track according to their own rules, such as if a string melody track is playing a long phrase, it might wait to change after that line is complete according to a rule set by the composer, while the percussion track might be allowed to change right away. Elias has a small AI that listens for "better" places to change, such as if the rule for the Trumpet track is to change on bar 5 beat 1 and the musician is slightly ahead of the beat, the system will adapt to that change point automatically.

MIDI and Audio

MIDI and Audio are the two most common representation formats of music that are handled by sound engines. The distinction is often important for sound engines as the type of adaptive operations that are possible in each representation are very different. In pre-recorded music referred as Audio, the adaptive operations are based on playback and mixing of musical clips. In MIDI (Musical Instrument Digital Interface) that sound is generated by sending performance instruction to an electronic synthesizer. The operation possible using MIDI includes control of individual notes and instruments, thus allowing change in the instruments that perform the music, as well as adding or removing notes using algorithmic methods. Historically, adaptive operations such as change in tempo or shifting the pitch of music were reserved to MIDI, but developments in audio signal processing allow today to change the speed of playback or change the pitch of an audio recording without changing the speed of playback with minimal audible artifacts. Other music formats, such as mod files that are used in music engines known as musical trackers, are also common in video games music. Mod files combine some of the aspects of recorded clips and note triggering instructions.

Algorithmic Composition Methods

An alternative or complementary method to horizontal resequencing and vertical layering that operates on pre-recorded materials, are so-called algorithmic methods that use computer code to generate music procedurally (Collins 2009; Duarte 2020). A possible distinction between algorithmic and generative methods is that algorithms often refer to rule based, largely deterministic operations that encode musical knowledge using formal grammars or other heuristic methods, while generative methods often refer to random generation or stochastic processes. Between the two extremes, many algorithmic composition methods combine both randomness and rules to create musical materials. Some examples of such combined methods are Markov models that may be constrained or learned from examples based on some underlying musical model, stochastic grammars, Augmented Transition Networks and Petri-nets, or abstract mathematical processes such as genetic algorithms, L-systems, and artificial life. One important aspect in using any type of procedural musical generation is the mapping of computational operations to musical parameters. Separate processes might be used to model rhythm versus note or pitch structures.

More recently Neural networks have become a focus of intensive research in music generation, where musical rules are learned implicitly from large enough corpuses of examples. Common methods for such learning and generation are recurrent neural networks (RNN), or combination of RNNs with variational models such as Variational AutoEncodersx1 (VAE), Generative Adversarial Networks (GAN), and more recently Transformers (Briot et al. 2019). These methods operate mostly in the symbolic domain. Automatic remixing of audio files can be done by applying string matching methods to sequences of features extracted from the acoustic signal. One common method is using a Factor Oracle algorithm to create an automaton structure according to suffix links connecting similar subsequences in the feature representation (Assayag and Dubnov

2004). Horizontal remixing is done by skipping the audio playback according to the suffix links that assures that the transitions are sounding smooth since they share common history. This method is operating according to a principle similar to a Markov model, except that the conditioning on the past can be of different length. Due to this property the audio remixing models are also known as Variable Memory Markov Models or Variable Markov Oracle (VMO) (Wang et al. 2017).

Middleware Software

Audio and Music Middleware are software tools, often developed by third parties that are not related to the game engine software, whose purpose is to help game composers and sound designers to create and integrate audio into the game. Most modern game engines, such as Unity or Unreal Engine, provision basic audio operations that allow direct integration into the game by direct calls to playback and mixing operations. The difficulty with working directly with game development software is that the compositional process is very different from the usual Digital Audio Workstation (DAW) software that is used for composing or producing music for non-game applications. Accordingly, one of the main advantages of Middleware is providing a more natural composition interface and easy work method for composers. Other more technical advantages of using Middleware are easy integration into major game engines without dependency on game programmers, high-quality audio with control of the audio footprint and support for various compression formats, integrated sound effect and support of audio plug-ins, multithreaded platform specific optimization, and so on. Some of the major names in the industry include FMOD, Wise-Audiokinetic, Tazman-Audio Fabric, Elias Software, and Criware (Nogueira 2019). In terms of adaptive music tools, some of the substantial differences between the different middleware are their level of support for MIDI and sound design implementation.

Historical Developments

Interactive sound in video games existed since Pong in 1972, mostly to emulate sounds of pinball machines in arcade games. Generative music in video games was introduced in Ballbazer in 1984 for producing music segments between games and menu (Plut and Pasquier 2020). The music was generated by a combination of short musical riffs for melody, bass, chords, and drums, with rules for choosing the next riff, the speed, and volume of music. The first fully interactive music system iMuse was developed and used in the game Monkey Island 2 in 1991 (Land and McConnel 1994). The system is based on symbolic music representation and implements a branching structure of adaptive music composition, where the decisions on which music to play and what transitions to make are based on the game situations and designed transitions between the scenes. DirectMusic by Microsoft is a low-level API that supports composition and playback of dynamic musical soundtracks based on stored compositional material. The system was first introduced in 1996 as part of the a DirectX library, and became part of Windows 98 Second Edition in February 1999, but was deprecated since 2000 with parts of it moving to other low level audio API, while some of the MIDI functionality remained in later DirectX versions. DirectMusic engine can be considered as an improvement on iMuse in terms of its ability to simultaneously play and manipulate musical events for vertical remixing, but it lacks support for the logical structure for horizontal resequencing of iMuse. Many other systems have been developed over the years, providing different levels of horizontal or vertical adaptivity, with various generative abilities and triggering logic control. For example, a recently introduced Adaptive Music System (AMS) (Hutchings and McCormack 2020) uses a combination of musical rules with agent heuristics for composing and arranging music according to emotional categories, which are linked to game object and game environment through a knowledge graph that is activated based on game actions.

Other Uses of Adaptive Audio

The idea of opening musical composition to chance operations and more recently to interaction with outside contextual information is not limited to video games. The field of music meta-creation explores the use of higher level constraints to guide algorithmic and generative systems according to user specifications (Pasquier et al. 2017). The field of Machine Improvisation combines machine listening with generative systems to create a real-time interaction between a machine and a musician (Wang et al. 2017). Automatic sound effect generation from video is being studied using deep neural networks that learn a mapping from video frames to audio, and using a video encoder to drive a neural network type of sound generator (Zhou et al. 2017). These works differ in terms of the specific types of objects they are modeling and level of synchronization between sound and image. Sensors and depth cameras, such as Kinect, have been used in experimental dance to generate sounds in response to movement (Berg et al. 2012). Other applications of adaptive music include theatre, circus, and various types of interactive multimedia, some of which is addressed by the IEEE 1599 standard for Multilayer Representation of Music Using eXtensible Markup Language (XML) (IEEE SA 2018). The focus of such applications is largely in regards to synchronization and logic of controlling different media assets during an execution of a complex but mostly linear presentation, with less emphasis on generative, algorithmic, or remixing (horizontal or vertical) techniques that are dominant in video games.

American Sign Language (ASL)

▶ American Sign Language Detection

American Sign Language Detection

Rupendra Raavi and Patrick C. K. Hung
Faculty of Business and IT, Ontario Tech University, Oshawa, ON, Canada

Synonyms

American Sign Language (ASL); Convolutional Neural Network (CNN); Mean Average Precision (MAP); World Health Organization (WHO); You Only Look Once (YOLO)

Definition

American Sign Language (ASL) detection is based on an object detection machine learning algorithm, which helps deaf and hard of hearing people in terms of communication.

Motivation and Background

World Health Organization (WHO) projected that by the year 2050, there would be around 2.5 billion people with some degree of hearing loss (WHO 2021).

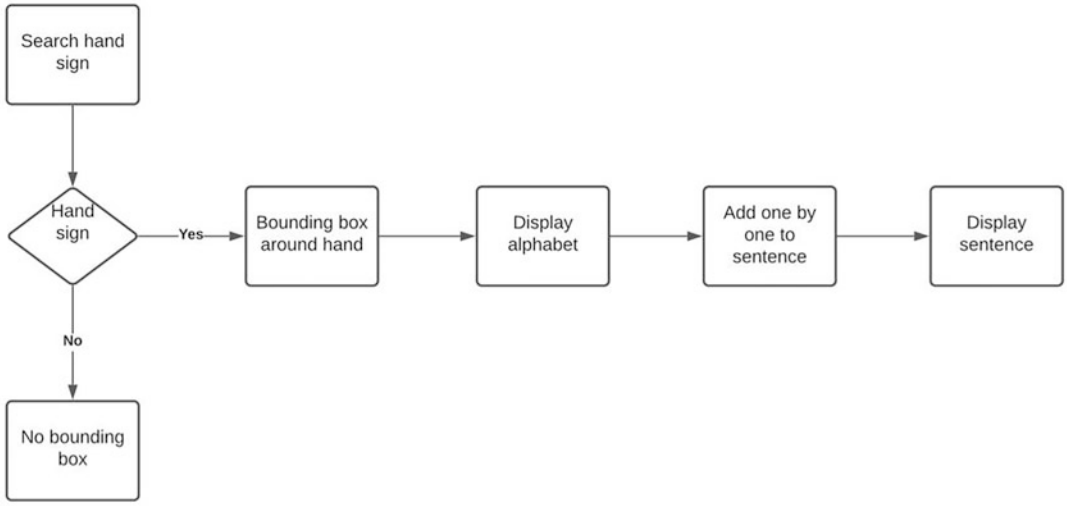
Most deaf anglophones adopt American Sign Language (ASL), which is a common "continental" language. On the other side, British Sign Language (BSL) and French Sign Language (LSF) became obsolete as people started to use ASL. The structure and rules of ASL were discovered in the 1970s and early 1980s. Manual communication was revived in the classroom as many artificial manual codes for spoken English or French. Since the late 1980s and early 1990s, deafer people have sought sign language instruction. Some schools are multilingual (ASL/English) and bicultural (Deaf/Hearing). For example, the deaf anglophone community in Canada uses ASL. Manitoba led the way in 1988, with Alberta following in 1990. Alberta added ASL to its provincial resolution. The Ontario Education Act was changed in 1993 to acknowledge ASL and LSQ as languages of instruction for deaf children (Carbin and Smith 2013).

Due to a language contact situation, ASL was born in the early nineteenth century at the American School for the Deaf (ASD) in West Hartford, Connecticut, in the United States. Since then, schools for the deaf community organizations have worked hard to spread the usage of ASL. Despite the widespread use of ASL, no reliable count of its users has been conducted. According to reliable estimates, there are between 250,000 and 500,000 ASL users in the United States, including a substantial number of children of deaf individuals (Carbin and Smith 2013).

ASL Machine Learning Model

You Only Look Once (YOLO) is a famous object detection algorithm with around 50 Mean Average Precision (MAP), which has a set of Convolutional Neural Networks (CNN) to help the algorithm extract the visual features of an image upon which it is being trained (Kuo 2016; Lu et al. 2020; Redmon and Farhadi 2018). Then with the help of these visual characteristics introduced to the model, the model detects the image in real-time videos/pictures. In this scenario, ASL alphabet images are trained, and then when these alphabets are shown to the camera, the algorithm will detect them.

Deaf and hard of hearing people usually communicate with a person with the help of an ASL interpreter. Due to the Covid-19 pandemic, everything turned out to be virtual, so using ASL interpreters appears to be more challenging. Still, hiring an ASL interpreter, for instance, is not always affordable. Hence, a machine learning model for ASL detection can help the deaf and blind communicate without the help of a human interpreter. For example, there are 26 alphabet hand signs for 26 alphabets and some hand signs for some phrases. A machine learning model such as the YOLO object detection algorithm can be built to detect these signs in real-time by computer vision (Ullah and Ullah 2020).



American Sign Language Detection, Fig. 1 ASL detection process by YOLO

The accuracy metrics used for YOLO are based on the intersection over union concept. The formula used to calculate it is the ratio in-between area of overlap and intersection area. Figure 1 describes the working of the algorithm initially. The machine learning YOLO-based object detection algorithm will look over all the frames coming through the live video, and then the frames will be split into the bounding boxes in the training phase. Then for every bounding box, the model will depict the output, for example, $4 \times 4 \times 18$ (similar to the one in the training phase). Here 4×4 is the grid used for the rectangular bounding box detection, and it is modified as per individual preference and application. The primary nine values will be correlated with the anchor box of 1. Here the immediate value will be the likeliness of an object within the bounding box. Values from 3 to 6 will be the bounding box coordinates for that image. The final three values will disclose where the actual image belongs. The coming nine values are for the anchor box of 2. At last non-max suppression is enforced over the depicted bounding boxes to get the individual depiction of the image (Sharma 2021).

Other object detection models include mobilenetssd, inception, vgg16, and efficient net. These models can be used to build a similar system, but YOLO usually outperforms all the other state-of-art object detection models (Liu et al. 2016). When the camera turns on, the machine learning model in the background will try to draw several bounding boxes and check whether any hand signs of American sign language alphabets are detected. If the machine learning model detects any hand signs, it highlights the hand signs with the bounding boxes and will display the alphabet of the detection. Next, the machine learning model highlights the hand signs with the bounding boxes and then will display alphabets of that detection. Each alphabet that is detected is attached to the top of the screen. Then the machine learning model will repeat the same process on all the frames coming out of the camera and find if any frame can match the hand signs of the ASL.

Synonyms

Murder-mystery; Party game; RPG; Social deduction game

Definitions

Social Deduction Game: A game genre that focuses on the use of logic and deductive reasoning to uncover a player's hidden role in a role-based game.

Murder-Mystery: A genre of fictional media that typically involves a crime or death that needs to be solved by the central character(s).

RPG (Role-playing Game): A genre of video games that allow the player to fill and act out certain roles the gameplay provides.

Party Game: A genre of games that facilitates social interactions among a group of members.

Introduction

Among Us is an online multiplayer game that incorporates the formats of social deduction, murder-mystery, RPG, and party game genres. The game was developed and published by the Washington-based American studio *Innersloth* on June 15, 2018, but did not reach popularity until mid-2020s (Carless 2020).

The game's popularity and player base, as of time of writing, continues to grow with the number of active players reaching 3.8 million by late September 2020 (Lugris 2020). A recent update reports that the game grew its user base 1600% in 8 months (Jain 2021). On *Twitch*, a platform where people can host streams and allow others to watch, *Among Us* is ranked third for the number of average viewers over the course of a week with 32,069,859 hours watched as of October 3, 2020 (SullyGnome 2020).

Robinson (2021) reports on the elicited emotions and engagement of the game and finds that compared to more photo realistic games, *Among Us* created consistent emotional reactions – dominantly excitement, curiosity, and relief.

History

Released in June 2018, *Among Us* was meant to be a local-multiplayer mobile game. Initially dubbed "*spacemafia*" on the *iOS AppStore*, the game had a poor marketing campaign and a very small player count. However, this small player count was very vocal about the game's

development, pushing the developers to continue to work on it even after the team's attempts to abandon the project. Throughout the year, *Innersloth* had released several updates leading up to the release of the game for PC in November 2018 and making it available for cross play between PC and mobile.

However, the game's current popularity is credited to the YouTuber and Twitch streamer *Sodapoppin*. He was among the first streamers to publicly show the otherwise unknown game. Other streams quickly followed, further boosting the game's exposure. Through the events of the COVID-19 pandemic forcing gamers to either watch or play more than what they previously could, the amounts of viewers and players for the game continued to skyrocket throughout the following months as it allowed socializing through the stay-at-home orders and social distancing regulations.

Gameplay

Among Us was heavily inspired by other social-deduction games such as *Mafia* (created by *Dimitry Davidoff*, 1986, as attributed by Haffner 1999) and *Secret Hitler* (created and published by *Goat, Wolf, & Cabbage LLC*, 2016), and provides an online multiplayer experience like other games of this genre like *Town of Salem* (developed and published by *BlankMediaGames*, 2018). However, a number of different traits make the gameplay unique and entertaining for both the player and the viewer.

The game offers three maps to play on: a spaceship, a headquarters, and an alien planet base (respectively named The Skeld, Mira HQ, and Polus), as well as a top-down view of the players and the map. The players can interact with the map by exploring and doing various tasks. Despite the top-down view, players have a limited scope of vision so they cannot see everything that other players do or where exactly they are. The game also offers customization to players, allowing them to change their color, outfit, and if they have made in-game purchases, their "pet" that follows them around the map. This differs from other social-deduction games as those characters are not as customizable or do not offer in-game interactivity.

There are two roles: the role of the Crewmate and the role of the Imposter. The objective of the game is for either role to win. If the Crewmates do all their tasks or vote off all the Imposters, then the Crewmates win the game. If the Imposters manage to kill more Crewmates than the number needed that can vote them off, or if a critical emergency timer on a sabotage event counts down to zero, then it is a victory for the Imposter (s). The number of Crewmates left surviving that would enable an Imposter win is one Crewmate to one Imposter. You can have up to three Imposters and a total of 10 players. The minimum number of players you can have in a game is four. Roles are randomly assigned each game. Imposters have a cool down timer for killing and for sabotaging the facility.

Upon finding a dead Crewmate left behind by the Imposter, all players will come together to discuss through an in-game chat client about who is or is not an Imposter in the duration of a limited time period. The Imposter's role during discussions is to lie their way through the game until the timer counts down to zero. People suspected to be Imposter will be voted off by the majority vote. Those who are not voted off continue into the next round and the process repeats again. Meetings can also be issued if the emergency meeting button is activated during gameplay.

Players who are not "alive" or were voted out still have an ability to play, providing another interactive experience different from other social-deduction games. These players appear as ghosts and are able to roam freely around the map and finish their tasks, which helps to aid in Crewmate victory. If the ghost has been an Imposter, they are still able to sabotage the map, but are unable to kill any living player. Deceased or voted off players are unable to communicate with the living but are able to communicate with each other through the in-game chat client.

Socialization

The event of the COVID-19 pandemic in 2020 has caused a shift in social dynamics and institutions. With the advocacy for social distancing, individuals were looking for other ways to communicate and conduct play. A popular outlet for this is video games and one of these video games is *Among Us* (Kriz 2020).

There had been not as much pressure in previous years for the need to socialize and interact with other individuals. While games have been partially viewed negatively before, 2020 has shifted opinions for many officials including the World Health Organization (WHO). In 2013, *gaming disorder* was added to the DSM-5, a collective medical source that describes a variety of disorders and ways to diagnose them (Petry and O'Brien 2013). However, during the pandemic, WHO strongly encouraged the use of video games during the pandemic, allowing a gateway for stress and anxiety relief and an outlet for social interaction (Snider 2020).

Following this, other social games like *Fall Guys* (developed by *Mediatonic* and published by *Devolver Digital* in 2020) and *Animal Crossing New Horizons* (developed and published by *Nintendo* in 2020) grew in trend. It is no surprise, then, that *Among Us* has reached among the top trending games of 2020. In fact, *The Guardian* offered *Among Us* as the "the ultimate party game of the paranoid Covid era" (Stuart 2020). *Among Us* strongly encourages socializing, and not just through its in-game chat client. *Discord*, a real-life chat client geared towards gamers, has hit a spike in downloads since *Among Us* reached popularity since players are utilizing *Discord*'s voice calling system in order to play the game together and make the game livelier with human voices. This encourages social interactions and social bonding with one another, a very important staple to mental health in 2020's world.

Playing over *Discord* and playing voiceless provides different experiences and methods. For example, playing the game through a *Discord* phone call will require you to time your speeches. Most players end up muting their microphones during gameplay until discussion meetings, as to not give anything away. Dead players can talk freely but must mute themselves when discussions are happening. There is a playing order when *Discord* is involved that is not present when players rely only on the in-game chat client – which does not utilize any voice activity and instead focuses on text-based communication. On *Twitch* streams and *YouTube* videos, evidence of one's guiltiness is also much more effectively discussed on a *Discord* call than it is in a game lacking verbal communication. Without verbal communication, members tend to form a bandwagon out of wild accusations just because someone said so with no questions asked.

Among Us has also made it into Internet meme culture and has given rise to a variety of artistic renditions, ranging from animated videos to people making their own Crewmate personas.

Analog Prototyping for Digital Game Design

Tonguc Ibrahim Sezen
Faculty of Communication and Environment, Rhine-Waal University of Applied Sciences, Kamp-Lintfort, Germany

Synonyms

Iterative game design; Paper prototyping; Physical prototyping; Prototyping

Definition

An analog game prototype is a nondigital preliminary playable object built to test various aspects of a video game. Analog prototypes are especially beneficial in testing the functionality and perception of core game ideas and mechanics in the early phases of preproduction. Analog prototypes may take various shapes such as board games, toys, and street games.

Introduction

Unlike other software, functioning as intended and being user friendly are not enough for video games; they are expected to be fun. As Ferrara points out, games are "inherently negotiated experiences; the designer normally just defines the parameters of play, within which the players bring the game to life" (Ferrara 2012), meaning the prediction of how a game will be experienced by players is quite difficult without seeing it in action. To reduce the risk of not being fun – meaning failure – video games are in need of being tested from the earliest possible step on. As an answer to this need, Salen and Zimmerman suggest an iterative approach to game design, a "cyclic process that alternates between prototyping, playtesting, evaluation, and refinement" (Salen and Zimmerman 2004). This methodology gives designers the possibility to evaluate and adjust their design at each new iteration. The process may start with low-fidelity analog prototypes right after the initial conceptualization and end with high-fidelity digital prototypes, which may even become the final product after refinement and polish. This article focuses on the analog prototyping phase of this process. Why and how do digital game designers use analog prototypes?

Why Analog Prototyping?

In video game design analog prototypes are usually built to test singled out game aspects which can be implemented without the aid of computation and are not expected to reflect other features of the project. A successful analog prototype is built quickly and provides "enough of an experience for someone to grasp the game [or tested components of it] and give feedback" (Fullerton 2014). Media-independent game mechanics may be tested using paper prototypes resembling card or board games (Rollings and Morris 2004), toy prototypes may focus on the playfulness of core mechanics (Gray et al. 2005; Macklin and Sharp 2016), and physical prototypes which are played like traditional street games may offer unique insides to the intended game experience (Adams and Dormans 2012; Waern and Back 2017). Not every aspect of a video game can be tested through analog

prototyping, but certain aspects of every game can be tested by it.

Analog Prototyping Process

Analog prototypes can be created using a wide range on objects. Some more or less standardized components for paper prototyping are meeples, tokens, index cards, tile cards, different types of dice, and of course pen and paper. Digital tools for creating printable graph paper or exporting data from spreadsheets into preexisting card templates can be used to quickly generate prototypes using data from early game documents. The tools for creating toy and physical prototypes are only limited by the goals and imagination of the designers.

Focusing on the iterative design of the overall gameplay experience, Fullerton proposes a four-step analog prototyping process which can be used in video game design (Fullerton 2014): The first step following the initial conceptualization is the "foundation" where the goal is the definition and design of basic game objects and the key procedures, or the core gameplay. The second step is "structure" where the designer starts building the framework of the game. By defining the essential rules and their structural roles in supporting other features, the designer builds an unfinished but functional game system. In the next iteration step, "formal details," new rules and procedures are added to the system to reach a fully functional game. The last step is "refinement" where the designers start to fill the details of the rough but playable system. After several iterations and answering key questions regarding the playability, designers can begin implementing their solutions in digital format.

Strengths and Limits of Analog Prototyping

Analog prototyping is a fast and inexpensive way of testing game ideas by turning them into tangible playable objects. Building an analog prototype forces designers to define game aspects, helps them understand the workings and perception of the game system, and gives them the opportunity to change any rule easily if they do not function as intended. Schell warns against the trap of falling into the temptation of overbuilding a prototype. In his words, a prototype "should be quick and dirty" (Schell 2014). They are test subjects created to be thrown away. According to Ham and Fullerton, compared to digital prototypes, analog prototypes are much easier for game designers to scrap, mainly because they require much less time and effort to build (Fullerton 2014; Ham 2015).

Some aspects of video games, such as game economy and resource management mechanics (Adams and Dormans 2012; Moore 2011), puzzles (Ferrara 2012; Moore 2011), and macro- and microspatial gameplay (Totten 2014) are considered more suitable to be tested through analog prototypes. They also provide a platform to balance statistics tough experimentation and to identify and close possible player exploits (Trefay 2010). Other aspects such as sensory experiences, mechanics involving continuous space and time, and game physics on the other hand are much harder to test trough them. Ham proposes a series of methods, such as creation of flowcharts or state charts to simulate AI and the use of simple heuristics to test motion, to translate video game mechanics into analog game mechanics (Ham 2015). Yet he also warns designers to question the usefulness of analog prototypes if such translations are required. Digital prototyping may be the most efficient way of exploring aspects requiring such translations.

Conclusion

Analog prototyping is especially beneficial in video game design education and in experimental game design. It is an easy, quick, and cheap way of focusing on and experimenting with game ideas without being distracted with complexities of the medium of choice. Despite its limits, its flexibility makes it applicable for the testing of a wide range of features of various types of games.

Animal Crossing: A Causal Game

Taeya Johnson[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Causal game; Real-time game

Definitions

Causal game = A game that is designed to be played occasionally for a relatively short period of time without losing points or competitive advantages

Real-time game = A game that uses real-world time instead of virtual in-game time

Introduction

During the COVID lockdown around the world, many people had resorted to video gaming as an escape into a new world full of many possibilities. One of the most popular games was Animal Crossing: New Horizons. This entry discusses the brief history of Animal Crossing and how Animal Crossing: New Horizons became hugely popular in 2020 during the pandemic.

History

Like Nintendo itself, the famous game Animal Crossing started in Japan with a man named Katsuya Egushi. In 1986, Egushi was able to obtain a job at Nintendo located in Kyoto, where he worked on many games and was known as a level designer for the well-known game Super Mario Bros. 3. Although he was making a name for himself at Nintendo, he was still homesick due to the relocation for his job, which led to the

creation of the first Animal Crossing being released in 2001 (Nintendo Life 2020).

In numerous interviews, Egushi stated that the game was a way for him to be able to recreate the feeling of being with family and friends: "Animal Crossing features three themes: family, friendship, and community. But the reason I wanted to investigate them was a result of being so lonely when I arrived in Kyoto…When I moved there I left my family and friends... In doing so, I realized that being close to them – being able to spend time with them, talk to them, play with them – was such a great and important thing. I wondered for a long time if there would be a way to recreate that feeling, and that was the impetus behind the original Animal Crossing" (Newton 2011).

As many people around the world play Animal Crossing, there is a connection with being able to play with friends and create a virtual world within it. While Animal Crossing is a relaxing game, there is more to offer while playing the game with many different characters and the opportunity to play online.

Gameplay

Animal Crossing has been around since the early 2000s, but the new series of the game became hugely popular years later during the COVID pandemic. While the world was in a lockdown and people were stuck in the house, the new release of Animal Crossing offered people a chance to escape reality and enter a relaxing virtual world. Although people were trapped in their homes and seeing friends was difficult, the game allowed the players to experience being with friends and doing activities through a console. The game became so popular that it sold more than 13 million copies within the first six weeks after its release (Huddleston Jr. 2020).

Animal Crossing is known to be a relaxing game. Not only can you interact with friends online, but players are also able to customize their characters and have endless tasks to help build their community. When the game is launched for the first time, you see an empty island with a character and a tent. Throughout the game, the character works on many tasks, such as building new tools and collecting certain items, to slowly build the island. As the game progresses, new tasks are required, and the players can travel to new islands to collect new materials, play with friends on their islands, and creating vacation homes for visitors. Figure 1 shows how the island looks when the game starts. Figure 2 shows the progression and aftermath of designing a client's dream vacation home.

Within the game, there are concepts that were put in place to help the players.

Animal Crossing: A Causal Game, Fig. 1 The island when the game starts

Animal Crossing: A Causal Game, Fig. 2 A dream vacation home

The first thing many people notice is that the game has a built-in clock that is accurate to the time in the real world. Not only does this help players not lose track of time, it also helps move the game along similar to the real world. For instance, if something is being built or mailed in the game, the players would have to wait a whole day until that task is complete. Along with the clock, the weather and region are also similar to where players are located in the real world. This gives players a sense of reality within the game.

Reviews

Animal Crossing: New Horizons was first introduced in 2020. With the pandemic trapping everyone indoor, the game prospered in numbers and sales. Many people loved the game right from the beginning with all the new things and creations within the game. Some said that after playing it for a while, they ran into a loop which consisted of running around the island, digging for fossils, and fishing on occasions. These chores seemed boring, but it did not last long. With each new update, new tasks kept players entertained. After the pandemic, the game continued to gain popularity as more people enjoyed the gameplay and used Animal Crossing as an escape or a comfort game.

Conclusion

In summary, the history of Animal Crossing started when a game developer left home and became homesick. The developer was able to turn his feelings of missing his friends and family into one of the top-selling games. The global pandemic further boosted its popularity and cemented its legacy in video gaming (Carpenter 2021; Claiborn 2020).

Synonyms

Life simulation game; Nonlinearity; Open-world game; Social game

Definitions

Social game: A social game (sometimes referred to as social simulation games) is a game in which one of the core themes revolves around maintaining and having meaningful social interaction with both NPCs (nonplayable characters) and other players if the game is multiplayer.

Life simulation game: Life simulation games usually have a focus on gameplay that allows players to have meaningful and complex interactions with the world around them. This interaction with the game's world usually addresses common life themes, such as farming, fishing, NPC social interaction, resource gathering, money-making, and many other themes found in day-to-day life.

Nonlinearity: Nonlinearity in games results in said games not having a set path for the players, and the game can be explored differently for all players. Games that do not fall into this category typically restrict the player to a strict linear progression during a playthrough.

Open-world game: Open-world games have a large, complex, and interesting environments for the players to explore and travel throughout. These games typically do not restrict player movement to a linear progression or path and allow the player to explore the openness of the world at their whim.

Introduction

Animal Crossing: New Horizons was developed and published by *Nintendo*, and it was released in March 2020. The game became extremely popular due to its long-awaited arrival, but it was also the beginning of the COVID-19 pandemic issues which forced many people indoors. Many players found solstice in the simple pleasures of this game, and it became one of the largest releases in recent years (Bogost 2020). The game was released solely for the *Nintendo Switch* gaming console. *Animal Crossing: New Horizons* is the fifth installment in the *Animal Crossing* series. The other games in the main series and the spinoffs are:

- Animal Crossing (2001, released for Nintendo 64)
- Animal Crossing: Wild World (2005, released for Nintendo DS)
- Animal Crossing: City Folk (2008, released for Nintendo Wii)
- Animal Crossing: New Leaf (2012, released for Nintendo 3DS)
- Animal Crossing: Happy Home Designer (2015, spinoff, released for Nintendo 3DS)
- Animal Crossing: Amiibo Festival (2015, spinoff, released for Nintendo Wii U)
- Animal Crossing: Pocket Camp (2017, spinoff, released for iOS and Android)

The game has an ESRB rating of E ("Animal Crossing" n.d.) as it appeals to almost all audiences and contains no adult themes. The *Animal*

Crossing series is known for its complex world building through its life simulation gameplay (Kim 2014); however, *Animal Crossing: New Horizons* builds upon this by adding an interactive and widely accessible multiplayer aspect. The core mechanic of the series is that the game time runs on real time which adds a more immersive layer of complexity to the series.

Gameplay

The gameplay for *Animal Crossing: New Horizons* is very simple and complex at the same time. The pace of the game is very relaxed and slow which allows for many things to be completed in one session while not feeling too rushed. There is a vast pool of activities that the player must choose from. The activities allow diverse gameplay that the player can decide upon. The open-world aspect of the game also allows the players to complete most tasks or activities at any point which prevents the game from feeling too restrictive or linear. The activities and tasks available to the player range from collecting fossils, fishing, catching and collecting rare insects, building relationships with player NPCs, foraging, collecting resources, earning money, and much more (see Table 1). The main "questline" of the game is progressively paying off loans to increase the size and storage space of your home.

Relative to other life simulation games on the market, *Animal Crossing: New Horizons* uses common themes and activities for the player that resonate throughout many other games in its genre. However, the unique spin that makes the game a one of a kind is its diverse and complex villager NPC system. As of October 2020, there is a total pool of 391 different and unique villagers in the game. Villagers are sorted into different personality categories that affect their dialogue and interactions with both the player and other NPCs. Villagers will slowly come to your island, and through the discovery of vacationing villagers on other islands, you also have the ability to ask them to join your island. This complex system allows for the player to decide what character traits the NPCs in their game have, and it allows for a more diverse and customizable world-building experience.

Animal Crossing: New Horizons and Its Popularity During COVID-19 Pandemic, Table 1 Activities in the game

Activity	Detail
Collecting	Fossils, fishing, catching bug and insects, foraging plants, currency, and recipes
Building	Town buildings, changing island topology, planting plants, and designing home
Crafting	Tools, furniture, clothing, and accessories
Character customization	Collecting and changing clothes, hair styles, and accessories
Travel	Visiting vacation islands and visiting the islands of other players
NPCs	Collecting/Inviting NPCs, gifting, trading, and building relationships

Reception and Effects of COVID-19

The reception of *Animal Crossing: New Horizons* was overwhelmingly positive due to both the quality of the game and the timeframe in which it was released. The game debuted on the market on March 20, 2020, and by the end of the month, *Nintendo* had sold over 11 million copies. In North America, the game became the best-selling title of March 2020 and the second-best-selling title of 2020 as a whole (Grubb 2020). As of June 30, 2020, the title has sold more than 22 million copies, making it the second-best-selling game on the *Nintendo Switch* system (Byford 2020).

Other than the quality of the game, the timing in which it was released played a significant factor toward its success. The game was released during the start of the worldwide COVID-19 pandemic. Many communities and players throughout the globe started quarantining, and the game provided an outlet for escape and relaxation that many individuals desperately needed during these times (Buchanan 2020). Although some previous versions of the game were offered to have

mechanics linked to addiction (Scully-Blaker 2019 on *Animal Crossing: Pocket Camp*), this specific version of the game offered players "temporary escape" from the risks of the pandemic, as well as a way to "get rid of loneliness" (Zhu 2020). Many individuals found interesting ways to use the game for events such as business meetings, weddings, birthdays, and much more. The widespread popularity of the game resulted in academic interest in its reception based on social sciences and humanities research (Leporati 2020). These endless possibilities and calming atmosphere for escape allowed for the game to become one of the most popular and impactful games of its time.

Definitions

Animation: is the emotional energy in motion of a visual thinking. The illusion of life by making sequential drawings (or 3D representations) of a continuing action and projecting their photographs onto the screen at a constant rate.

Neurocinematics: refers to the neuroscience of film, term coined by Uri Hasson from Princeton University, who studies the effects on the viewer's brain activity when watching a given film.

Introduction

Why does it matter what we know about emotions when making movies? Can an animation help us to understand them better? Even if we naturally learn by telling stories, people may forget words and events, but they will never forget how something makes them feel. Movies touch our hearts in the same way they touch our minds.

> Whether we hope to spot concealed emotions or seek compassionate connection, our ability to see and respond to others' often unspoken feelings is central. This ability can be trained. We provide the tools. Paul Ekman

The use of animation as a creative media to enhance communication implies to study relationships, how we connect with each other and how our brains make connections with the information that collects. Neuroscientists acknowledge that we humans need to make sense of our reality, for what we make relationships depending on our perception (Beau Lotto 2015). The dangerous and magic point of this fact is the brain does not distinguish between the imaginative perception from the real perception. If our well-being depends on how we see, perceive the inner/out world, we need to experiment and study how we make stories in order to deconstruct them and get to observe from different angles, not just one reality but may be many others.

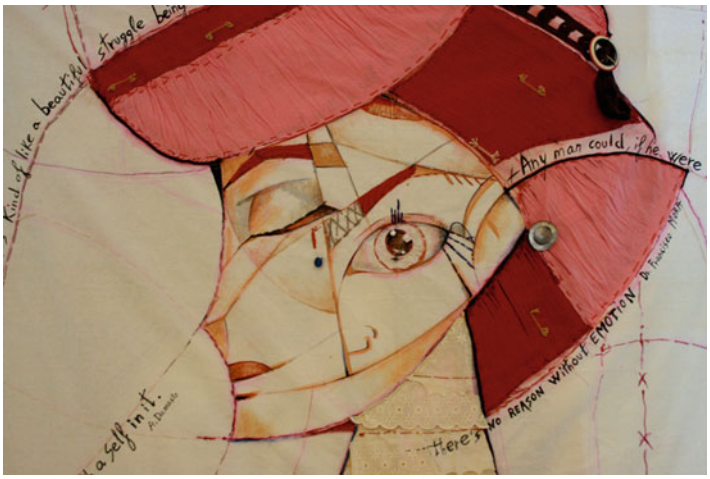
Emotional regulation is extremely relevant since influences our decision-making and problem-solving skills. Our well-being or happiness depends on this mysterious ancient world of emotions connected to our way of thinking, and we can explore it through animation. Studies from Talma Hendler, Zack Jeffrey, or Uri Hasson evidence of how watching movies activate specific areas in our brain related to different emotions. This new neuroscience of film making is known as Neurocinematics (Hasson 2008). There are no specific studies regarding to the positive effects of the creative process of animation, especially focusing on how animation and emotions are connected during the art production.

Labs such as Lotto Lab in the United Kingdom, the Animated Learning Lab in Denmark, or the Film Board of Canada have been working on this issue by developing new paradigms of teaching connected to sciences and film production. They include into their teaching human values such as mindfulness, compassion, resilience, and emotional intelligence. We consider animation as a social emotional learning tool; animation is the emotional energy in movement that provides the illusion of life, a soul, and a fantasy world as real. It is an artistic thinking-feeling media, which provides great opportunities to experiment, by playing, with different perspectives, creativity and innovation, and new worlds.

Before going into the current fascination with visual effects and the most advance technology in movies, we should recall how the art of film making started with silent feature films such as from Méliès, *A trip to the Moon* (1902) or Chaplin's *The Kid* (1921). In these films as many others of that time, the main tools that directors could count on, to show the audience an idea or feeling, were the movement, action, and music before dialog appeared. Animation happened even before those movies were produced, in the Upper Paleolithic caves of Altamira or Chauvet (France, ca. 30000 BC). Those were the first attempts to express the idea or feeling of how an animal look like, furthermore, in movement. Some anthropologists and psychologists of neuroaesthetics as Marcos Nadal (University of Vienna 2014) believed that those representations were probably like plays where they could rehearse a situation like hunting. Those cavemen were learning through visual storytelling, most likely making their own sounds and pantomime, before any language existed. They made

Animation and Neurocinematics: Visible Language of E-motion-S and Its Magical Science, Fig. 1 Film animated strip

Animation and Neurocinematics: Visible Language of E-motion-S and Its Magical Science, Fig. 2 Textile art for a character design. Re-construction of thyself



associations between what they saw and the drawings on the walls with a meaning.

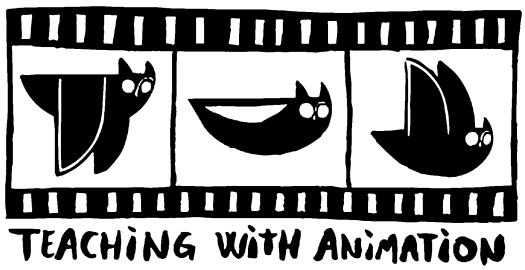
Animation can be as abstract as in its origins and go beyond the limits of the physicality of live action movies, for which we usually see a hybrid of productions that need animation to recreate the impossible scenarios that we imagine in our brains, such as *Avatar* (James Cameron 2009) or possible recreations from the past, such as *Jurassic Park* (Steven Spielberg 1993). Directors like Ray Harryhausen (United States) and Jan Švankmajer (Czeck Republic) were experimenting live action with animation before big companies like Disney produced the well-known *Mary Poppins* (1964), *Who Framed Roger Rabbit* (1998), and *The Three Caballeros* (1945). Animation acts as the bridge between reality and fantasy, and the imaginary perception and the real perception. It makes us believe the most abstract forms or realistic dreams as real life, thanks to the emotions which connect us. The short movie *The Dot and the Line: A Romance in Lower Mathematics* (Chuck Jones 1965) is a very harmonic story where we see through the simplest elements of visual composition, the pure expression of feelings in movement.

In the following lines, we will briefly present the relationship between animation, neuroscience, and emotions, which we use during film productions at different levels. We obtained very positive results that motivate us to share and ask scientists to keep working with artists, like Paul Ekman who has explored with his studies the universal signs of emotions and facial expressions in different cultures. Antonio Damasio pointed out that scientists record life as it is; yet, artists express it as it may or may not be. Artists can be the scientists of pre-conceiving life.

> "The greatest scientists are artists as well" Einstein. (Calaprice 2000, 245)

This is our vision, how we can use the knowledge of producing movies to change our perception, to learn about life understanding our emotions, so the relationships that we have with the *self* and the external world (Fig. 2). Rewire our brain with a tool that helps to rewrite our story to become fully alive and make sense of our lives.

Methodology: Working Beliefs-Feelings-Actions Through Animated Productions



In this section, we share our observations and work method during the creative process of making an animated film.

We collected data from the Animated Learning Lab in collaboration with educational institutions from different countries, such as San Carles Fine Arts in Valencia, Spain; independent artists such as George Mcbean (UNICEF) and creative professionals, who have been working on tailoring animated workshops for students of different ages, from toddlers to postgraduate students. This makes a richer experience at the time to exchange and contrast ideas, which shows us interesting ways in which animation is a very powerful tool for building social relationships and increasing creativity. To answer why we connect animation, emotions, and neuroscience, we will start explaining the relationship between our brain and emotions.

Scientists such as Richard Davidson (University of Wisconsin) Daniel Siegel (Mindsight Institute, California) or Joe Dispenza (DC) have been studying neuroplasticity and researching the effects of meditation and emotional regulation for an optimal learning and well-being. As we mentioned before, emotions affect our decision-making, if we learn how to identify the emotions and regulate them, we will be able to develop resilience and increase our sense of fulfillment and contentment. We found that animation can be an excellent media to learn and regulate our emotions, understand different perspectives, and be more conscious about our feelings and beliefs.

The most recent Pixar movie, *Inside Out* (2015), is an excellent sample of the importance to understand the relationship between emotions and thoughts with behavior. Furthermore, some schools are using the movie to talk about and identify the emotions. By watching this movie, we learn to identify four from the primary six emotions that Antonio Damasio classified in his research (Damasio 1999). We get to know why and how the characters behave, what is inside our heads and what kind of feelings and actions emerge when one emotion is in control. We understand the importance of accepting and balancing negative and positive emotions because they need each other. The same thing applies to the question of being more rational or emotional; both go hand-in-hand and work together as we can see in *Reason and emotion* (Disney 1943). Some great films as *Party Cloudy* (Pixar 2009) explore feelings and ideas, friendship and resilience, with a clear reflection by using images over words. *Luxo Jr.* (Pixar 1986) was a revolutionary experiment using procedural animation, where John Lasseter applied the classical principles of animation to 3D characters in order to provoke emotions. Most recently, in the independent film-making arena, we find a movie which has a program for teachers to share wisdom about life, *The Prophet* (Salma Hayek 2015).

The field of neuroplasticity explains how our brain is capable of change with every experience and by repetition, creating new synapses and patterns that can determine new behaviors (Davidson 2008). Animation is all about repetition and focus; it is a transformative process where we work connecting our minds to our bodies. During any creative process, the energy flows where our attention is focused (Mihaly Csikszentmihalyi 2008); some people are more kinesthetic, others are attracted to sound or are more verbal; these are some of the multiple intelligences that Howard Gardner (Harvard 2006) acknowledged, all can be explored during the creation of an animated movie as if it were a mindfulness practice.

Animation can be a practice of mindfulness, since animators need to observe outside of themselves, in order to be able to understand the character that we must animate, or have enough

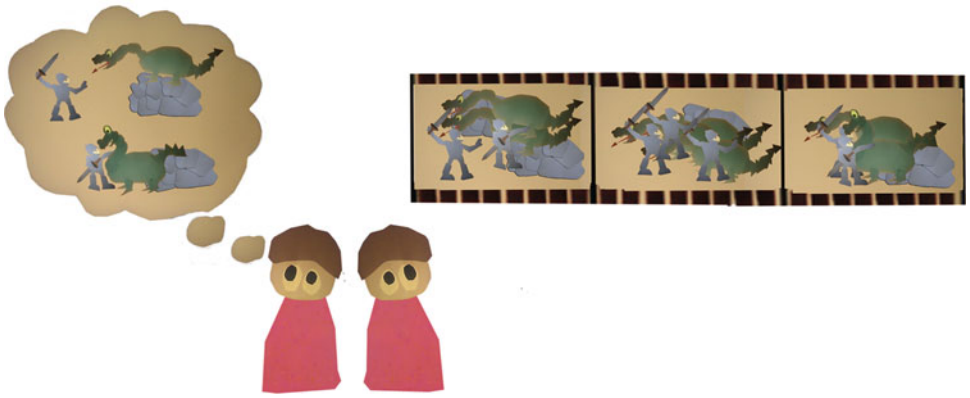
information to be able to design a new original character, environment which has to be believable and engaging to the audience. This engagement happens because our empathy and mirror neurons activate when a speaker and listener interact (Hasson 2010) (Fig. 3). Despite very subtle differences between cultures, is our basic human essence to connect through empathy; Paul Ekman (*Emotions Revealed* 2012) has been working for major animation studios due to his relevant studies about facial expressions, emotions, and deception. Animators have been using his knowledge to better understand the nuances of expressing feelings within different contexts and situations. This is relevant to exaggeration and having gestures to entertain the audience, as the story unwraps. Our understanding about the story itself is a reason for case study; to question beliefs, decide which emotions intervene and what actions are going to happen to resolve the conflict. Life is presented as a conflict to resolve, with a touch of imagination. Walt Disney Studios used to test future animators with an assignment where they had to express different feelings and emotions using a sack of flour. A clear sample of how we can learn about emotions from the inside out is by doing, as we do from outside in, by watching movies.

To work on a production, we set up groups of three or four students, depending on their age and interests. Each group had to discuss an idea and make a film out of it. Different roles were distributed amongst themselves, if they are not children under 9–10 years old. Ateliers are taught in a constructivism learning method (Vygotsky), to animate in a very intuitive way, by playing with the software and receiving small lessons and support from the tutors. We focus on four main animation techniques: pixilation, cut out, clay, and 2D, to keep them in touch with analog materials and avoid working just with computers. We encouraged the importance of using kinesthetic techniques when possible, since it helps to focus. The rewarding system of the brain activates when students see a physical and visual product after their learning experience.

Animators develop the four main components that Daniel Goleman acknowledges in his definition of emotional intelligence (2005): self-awareness, social awareness, self-management, and relationship management.

Naturally our brain is plastic and shapes itself by experiences; it is always transforming and creating new synapses, even as we get older. When we work on making movies, we put ourselves as directors or animators in hypothetical situations that, either, are real memories or fantasies. In either case, they are an excuse to experiment in a safe context, situations which we could be involved in, provoking: reactions and, inducing feelings and ideas that we can question by reflecting, especially working in groups where different perspectives are factored in.

The creators have to think and feel the way their characters must behave. During this process,



Animation and Neurocinematics: Visible Language of E-motion-S and Its Magical Science, Fig. 3 Illustration of speaker-listener when telling a story

they are not just ***passive*** **observers** but ***active*** **protagonists**. As a result, the learning experience is stronger and their effects are more intense regarding comprehension to why a character acts in a certain manner, and how they should express ideas and feelings in accordance with that behavior. The results in comprehension of emotional status are higher than when watching movies. While watching a film, each viewer makes a lecture of the scene based on his perception (from his/her background). In other words, they bring their vision from what they personally have lived; by doing animation, they *become* the character, forcing them to get his mindset with all its traits. Feelings are no longer a personal interpretation but a rehearsal for *being* the character, even though there may be certain level of subjectivity while acting.

Animation acts as a metaphor to transport the ateliers to live other people lives, through their minds and bodies. We usually hear" You don't understand because it never happened to you" and somehow this is true since the process of embodying feelings and ideas is always more real when one has lived a similar personal experience. The reason is there is a trace of that past event through all the senses, instead of being just a hypothetical thought or imagination. In this matter, the creative process is more important than the quality of the final result, because it makes you gain knowledge by experiencing instead by just listening or viewing (Fig. 3).

At the end of the production students, learn technical aspects related to animation and film making than can be applied to reflect on real life. Movies are audiovisuals expressions from reflections about life, a work in progress; and we create our own stories as recreations of past, present, or future events. We become the architects of personal realities, by editing those moments and putting them together to make sense of what we live (Lev Kuleshov 1920). Our brain does not distinguish what is real or fiction, and perception and cognition are crucial in understanding emotions and getting an optimal communication within the self and others. We edit and change our realities due to personal perception and the fragmentation that occurs in our brains when processing data; this is a whole new area of study, the cognitive neuroscience of film (Jeffrey Zack 2014).

> Life is a tragedy when seen in close-up, but a comedy in long-shot. Chaplin (1889–1977)

In making movies, we must be aware of the meaning and function that every artistic component adds to the film. In animation, we work with what big studios call color script, which shows the film's colors and lights visualized in key frames from the primary scenes. Nowadays, we can find the whole movie compressed as a *barcode*, providing the whole spectrum in one image. Animators learned to evoke emotions by using different technical elements of composition such as color, warm for love and positive feelings, more blue or darker for sad ones: in *Beauty and the Beast* (Disney 1992) the castle changes from very dark bluish colors during the spell, to bright and warm towards the end of the film. Round shapes are more suitable for children; they are soft and calm as we see them in *Lilo ad Stich* (Disney 2002), while more angular shapes convey a cold and aggressive feeling. More light is associated with happy and relaxed situations, such as in *Tangle* (Disney 2010) where everything is inspired by the painting of Fragonard; the main colors are pink and soft with an especial glow. Music is extremely relevant as well as many other elements, such as rhythm. Animators and directors start to be more aware of the psychological and symbolic meaning of these components as they work on productions. Even camera movement can create and enhance different moods.

To summarize, life in animation is a safe game where we play somebody else; we are free and focus on what we do. Being aware of what happens brings a more peaceful status of relaxation to face problems and make decisions. We work on resilience and the relationships between the world and the self, as well as the connections between our thoughts, feelings, and actions, in order to reach balance. Animated movies can teach us how to feel like children again and inspire us to become our better selves, even when we are already grown-ups thanks to neuroplasticity. It is a chance to find ourselves in somebody else's eyes, so we can meet others within ourselves by

empathy, which is the key to our emotional system. Animation is an excellent art form for self-awareness and self-development, which we can use for children and adults. Filmmakers and professionals of other visual fields must take bigger responsibility of their influence in people's lives, through their movies, especially children. Animation is more than an entertaining media; it is a visual language of emotions and feelings, worth to research the sciences of its effects in how we make up stories in our minds in order to make meanings and sense of our lives, starting by how we perceive the world.

Results

- Animation improves our cognitive functions and awareness of being.
- Students or professionals learn about emotions and feelings (especially the difference)
- It enhances social skills such as cooperation, compassion, tolerance, listening, and teamwork.
- Animation provides a more natural method to reflect on actions by having fun, without judgment.
- Communication becomes better within the teamwork by sharing and listening.
- Expressing feeling through animation encourages students to find their voice when there is some impediment or difficulty, physical or psychological.
- The students raise their self-esteem and feeling of reward by producing a final product.
- Learning skills, as concentration, focus improve considerably after a program is complete.
- Students start to develop a personal mindset with a critical view to question audiovisual information and beliefs systems.
- Animation students get greater knowledge and comprehension of visual literacy when watching or producing movies.
- Creativity increases in all cases, including the most introverted animators.

Conclusions and Discussion

Working with animation provides the tools to train our minds and bodies thanks to neuroplasticity, by applying the emotional intelligence. It can be considered as a medium for cognitive therapies.

It is a bridge between sciences and arts.

Animation is an excellent medium to teach visual literacy and develop critical minds to avoid manipulation.

Within art therapy, it works as an excellent new approach with autistic children and any other condition that is an obstacle to communication.

It is a mindfulness media and tool to put it in practice and bring consciousness from the unconsciousness.

The creative process of an animated movie helps to develop important social skills.

Animated movies serve as metaphors to communicate when language barriers are an impediment. It can be an alternative language to linguistics.

Animation should be considered a social emotional learning tool to be incorporated in regular curricula to implement knowledge about emotions.

Animated productions open new ways of communication, contributing to the creation of happier communities with the necessary tools to obtain an optimal sense of resilience, in order to cope with life's challenges, learning to be humans. Animation is a social emotional learning media, extremely powerful to study deeper the cognitive effects in our brains and minds during art production, which can bring us a better understanding of how we see the world from different perspectives.

Animation can be an important storytelling media to be aware of our thoughts and feelings, to reflect upon them and understand the stories that our brain creates, since apparently its default mode activity is story-making (Mehl-Madrona 2010).

> I am convinced that animation really is the ultimate art form of our time with endless new territories to explore. Glen Keane. http://www.awn.com/news/glen-keane-creates-nephtali-short-paris-opera

Synonyms

Social engineering attacks, Spear phishing, Phishing attacks, Cybersecurity attacks, Phishing and game attacks.

Definition

Phishing is a social engineering attack which aims to manipulate people and encourage them to expose their confidential information. There are many different types of phishing attacks such as spear phishing, whaling, vishing, and smishing.

Introduction

Cybercrime is becoming a widespread problem that is posing an increased risk due to the increasing number of devices such as smartphones that are connected to the Internet. There is an increase in the usage of smartphones for a variety of applications, such as browsing the Internet, gaming, social networking, online banking, and attending to emails. The past three years have seen an increase in smartphone usage for email applications by 180% (Heinze et al. 2016). Furthermore, banking users will use their mobile devices to manage their current accounts over 2.3 billion times – more than the cumulative total of desktop PCs, branch, and telephone banking users (Heinze et al. 2016). However, less than 33% of mobile users have installed antivirus software on their devices when compared to the 91% level seen for laptop users. One reason may be that 45% of mobile users do not see cyberattacks on their mobile devices as a threat. The rise in the use of smartphones, their limited security, and the lack of end user knowledge increase the risks of victimization. This directly affects the gaming applications while using smartphones.

Phishing is one of the social engineering attacks which is the psychological manipulation of individuals into revealing confidential information (Anderson 2008). Phishing is a common form of identity theft and it is among the highest-ranked cybercrimes, costing organizations an average of $3.7 million per year in USA (Greenberg 2016). A study by a British government–backed cybersecurity firm found that phishing attacks cost British users £174.4 million in 2015 (Greenberg 2016). The most common phishing uses emails, chats, or websites along with attacks game applications especially among online and network games to get valuable information. A phishing attack disguises itself as a harmless request from a trusted sender that tricks its victim into sharing personal information. It can be thought of as an attack that uses social engineering to target the gullibility of people. Social engineering is "the use of non-technical means to gain unauthorized access to information or computer systems" (Thompson 2006). Phishing attacks are in theory a well-engineered social attack to extract valuable personal information from individuals. Phishing attacks tend to be challenging to detect by inexperienced people. This is due to the fact that they pretend to be coming from well-established and trustworthy senders (Thompson 2006). Most people assume that phishing attacks are aimed to financially damage individuals alone. That may be true; however, their damage is actually far more deep rooted and long lasting. This is because, individuals who have been harmed have their trust significantly diminished in electronics and

business from which the phishing email appears to have come (Robila and Ragucci 2006). This in turn means the reputation of that business will be damaged, causing loss of its loyal customers, since those customers tend to associate the business with phishing attacks and ceases to use the services offered by that business (Sullins 2006).

An investigation by McAfee illustrated that employees working in finance, accounting, and human resources were among the worst in detecting phishing attacks and responding appropriately to them (Cochin et al. 2014). This then raises the question of how such departments, with so much access to sensitive data, should guard their organization against phishing attacks. Multiple sources from renowned scholars strongly believe that the best way to defend against such attacks is by using a multilayered technical anti-phishing defense system. Nevertheless, the biggest part of this defense mechanism still remains well educating and training employees of an organization to be able to recognize phishing attempts and immediately respond by reporting them to the members of the IT team (Butler 2007; Hong 2012; Swapan 2012).

Due to the severity of cybercrime at personal and national levels, many countries have introduced cybercrime laws. In the UK, Sections 41–44 of the Act, which amends the Computer Misuse Act 1990 (Thompson 2006), stipulates that offenders will face tougher penalties for committing cybercrimes intended to cause serious damage. The US Computer Fraud and Abuse Act (CFAA) was enacted in 1986 and its penalties can be imprisonment for not more than five years and/or a fine of not more than $250,000 for individuals (Robila and Ragucci 2006).

Gamification Solution

Phishing has been a complex phenomenon and therefore it is not possible to single out a solution to avoid it. Therefore, the risk of phishing can be reduced through the education and training of users and by suitable technology.

There are numerous technical and nontechnical solutions that have been suggested to reduce the risk of phishing. The solutions are based on the latest studies in the field in addition to the best practices and awareness in the field. E-mail phishing attacks have evolved from being purely technical, consequently highlighting the need for defense mechanisms that go beyond purely technical controls. Thus, security in this application must be viewed using a holistic perspective to integrate technology with aspects of human behavior.

A survey of the market reveals that there are many commercially available solutions tailored toward fighting fishing attacks. Despite their widespread availability, tools to detect automated e-mails have limited capabilities (Fette et al. 2007) (Zhang et al. 2007). conducted a study on ten anti-phishing tools and found that only one of them was able to correctly detect 90% of automated emails in a certain trial. However, a further investigation showed a false classification accuracy of 42%, implying that it incorrectly classified 42% of emails. The reason for this difficulty in detecting potential phishing attacks is that phishing attacks are constantly evolving to take more complex forms. As a result of this, it is very difficult for universal anti-phishing tools to detect and protect the user from all forms of attacks (Zhang et al. 2007). Instead, the readily available tools merely reduce the risk of phishing attacks without offering a comprehensive and accurate detection of all possible attacks (Dodge Jr et al. 2007) (Dodge and Ferguson 2006) (Downs et al. 2007). classifies the incorrect detection of legitimate and phishing emails as being false positive and negative, respectively. They also found that anti-phishing tools can never give complete protection against either form of false detection of emails. Therefore, users should make their final decision on the potential classification of emails using their own knowledge and experience rather than solely relying on the anti-phishing tool. This can prove to be a challenge as user behavior and knowledge is unpredictable and there is no systematic way to remove the risk associated with a lack of appropriate user knowledge on the matter (Dodge Jr et al. 2007). This shows that complete protection is only achievable by having an idea of the behavioral response of a user, be it through education or

knowledge of the best practices. It is thus important to understand what exactly makes people susceptible to phishing attacks to help us develop all anti-phishing tools, most importantly awareness and education of the issue (Kumaraguru et al. 2007; Sheng et al. 2007). Further research in the vulnerability of users to phishing attacks is needed to develop complete anti-phishing protection tools that can offer an end-to-end solution against a variety of phishing attacks.

Despite the reduction in the potential of phishing attacks offered by technological solutions, user-level protection still proves to be the most effective form owing to their high vulnerability due to a lack of knowledge in the field (Downs et al. 2007). This claim is proved by many researchers in the field who conclude that there is a definite need to improve user awareness on the matter to increase the chances of success of fighting against the attacks (Downs et al. 2007) (Kumaraguru et al. 2007) (Sheng et al. 2007). A study conducted by (Forte 2009) finds that relying solely on technological barriers against phishing attacks offers limited protection as the attacks are typically designed to work directly on users and exploit their lack of knowledge. This shows that it is of utmost importance to educate users on the importance of verifying the legitimacy of phone calls and emails that they receive. Phishing awareness has been discussed extensively in the literature, with some sources referring to recommendations known as best practices that users can follow to limit their exposure to potential attacks. They also discuss how these best practices can be taught to a wide audience in an effective manner.

"Gamification is defined as a process that integrates game elements into game fewer objects in order to have graceful characteristics" (Yohannis et al. 2014), this means that gamification uses game elements (badges, levels, time constraints, etc.) in a nongame environment to make the system have graceful characteristics, meaning it is not a full game. It only uses elements from games. Deterding et al. (Deterding et al. 2011) say that gamification refers to the use, design, elements, and characteristics of games in a nongame context. This means that gamification is in between a full game and parts, gaming and playing.

A way to play a game while having fun, but it is not a full game. The effectiveness of teaching procedural and conceptual knowledge using games has been discussed extensively in the literature (Rittle-Johnson and Koedinger 2002; Gee 2003).

Researchers have put forward several blacklist−/whitelist-based and heuristics-based defense mechanisms to protect against phishing. Entities such as PhishTank (PhishTank) and Anti-Phishing Working Group (APWG) have compiled reports on authentication services and phishing. Over the years, many tools have been developed which are designed to safeguard against the most common phishing attacks: browsing services like Microsoft SmartScreen Filter, Norton Safe Web, McAfee SiteAdvisor, and Google Safe Browsing are just some of the tools developed to this end. Nonetheless, phishing practices have evolved in sophistication in tandem with defense systems, often staying one step ahead in the game of avoiding notice and bypassing safeguards (Yue and Wang 2010). The struggle between phishers and anti-phishers is an enduring one.

Anti-Phishing Phil

Sheng et al. (Sheng et al. 2007) presented the development of an online game called "Anti-Phishing Phil." Anti-Phishing Phil is a game developed to educate users about phishing. This game teaches users how to spot phishing attacks. The player (user) is playing as a fish named Phil. Phil is hungry and wants to eat worms, so he can become a bigger fish. The problem is that the worms are associated with URLs. These URLs can be either to legitimate websites or to phishing websites. The player needs to choose the right worms to eat before running out of time. Phil's father is guiding the player by giving tips on how a user can detect phishing URLs, thus using entertainment for the purpose of educating the users about phishing. Anti-Phishing Phil uses rounds, scores, lives, and time for the purpose of entertainment. If the user chose a good URL, then the user is going to achieve points. If the user chose a phishing URL, then the user is going to lose

points. This is with the purpose of educating about phishing threats.

Users can be educated by means of a game to enhance the learning process (Sheng et al. 2007). For instance, they can be presented with a series of URLs: they gain points for correctly identifying safe URLs and lose points for clicking phishing links. The results of the game carried out by (Sheng et al. 2007) showed an increase of 60% in the detection of phishing links, thereby showing the successful transfer of knowledge of phishing attacks onto users. Another example of a study that aims to educate users using a game is done by (Zhang et al. 2007). This game gives users clues on how to identify URLs that can potentially be used for phishing attacks, such as teaching users to rely as much as possible on the links on the first page of search engines as these are typically the most reliable ones. Despite increasing the user awareness toward potentially harmful URLs, a limitation of this approach is that it relies solely on detecting the legitimacy of the URLs without making reference to the detection of actual phishing messages. The outcome of the game was also determined using a scoring system to increase user interest in the issue. Teaching the concepts using this interactive approach (as shown by (Sheng et al. 2007)) aims to educate users in a dynamic manner where they aim to score the highest score possible, thereby increasing user interest in the underlying concepts aimed to be taught and overall retention of information (Quinn 2005).

Mobile Game

A new mobile game, at a prototype level, is developed by Arachchilage et al. (Arachchilage and Hameed 2017) with the aim to teach and train individual's minds to defend themselves from the different techniques used by phishing attacks. This game is centered around the purpose of improving the user's behavior toward subconscious detection of the threat of the phishing attack and hence avoiding it. The study on the effectiveness of this mobile game on teaching ordinary people to thwart phishing attacks has shown a significantly promising result. The study further brought to attention that the avoidance behavior of individuals was heightened by the individual's own threat perception, perceived severity, perceived susceptibility, self-efficacy, and safeguard effectiveness. This is while the cost of safeguarding provided an adverse impact.

"Smells Phishy?" Board Game

On the front of anti-phishing, board games have been developed to increase the player's awareness regarding online phishing scams. One particular board game, by Baslyman and Chiasson (Herzberg 2009), was used in the study which showed people who played the game now better understand what phishing scams are and how they can best avoid falling into their traps (Arachchilage and Hameed 2017).

Embedded Training Email

Kumaraguru et al. (Kumaraguru et al. 2007) have invented and developed a new technique called embedded training email system, in the quest to teach people how to protect themselves against phishing attacks, focusing on the use of email. Further experiments have illustrated that two embedded training designs work much better than the current use of sending security notices (Arachchilage and Hameed 2017).

Automatic Content Generation

Tseng et al. (Tseng et al. 2011) have focused on a game project that turns the assessment of the content of a website into a game in order to teach users how to detect phishing. This includes describing stereotypes features of a phishing attack by coming up with a hierarchy frame for the phishing attacks. Furthermore, other properties of the frame model, such as its instantiation and inheritance, enable the extension of the phishing pages, which in turn increases the game content. The test on the effectiveness of this technique was carried out by the use of an anti-phishing educational game, which resulted in most experts and participants satisfied with this system.

Self-Efficacy

Archchilage et al. (Arachchilage and Love 2014) have intercalated both conceptual and procedural

knowledge into their innovation approach into gamification. This focuses on their effect on the player's self-efficiency to avoid phishing attacks. Therefore, the aim is to add self-efficiency into the game frame in order to make the game better equipped for teaching anti-phishing techniques. However, this comes with the challenge of actually making a successful transplant of self-efficiency into the body of the game. This is achieved by teaching individuals how to well differentiate true URLs (uniform resource locators) from fake ones, using elements from a theoretical model (Lin et al. 2015). This model has continually shown that the interaction of conceptual knowledge and procedural knowledge tend to produce a positive effect on an individual's self-efficiency when it comes to avoiding phishing scams.

PicoCTF

A new and innovative competition has emerged among high school computer science enthusiasts, called PicoCTF (Chapman et al. 2014). Unlike conventional computer games, this competition is aiming to broaden the student's understanding of computer security, through a series of web-based game challenges. PictoCTF is based on the idea of capturing the flag. Teams race to solve computer security obstacles, looking for a digital "flag," encrypted in text or a binary program and saved in an unknown server. Although the competition can last for a couple of days for a team to win by discovering the exact location of the flag, the many challenges faced by the competitors and the array of solution they come up with will allow them to learn crucial skills in computer forensics, cryptography, web security, reverse engineering, and binary exploitation. This game is both an entertaining, challenging yet legal way for both students and tactically professional experts to practice and improve their skill in a computer breach, which in turn will give them a better understanding of how breaches can happen and how to avoid them.

Control-Alt-Hack

Meanwhile, Control-Alt-Hack is a new design of card game also aiming at increasing awareness of computer security by changing people's understanding and discipline (Denning et al. 2013). The players of the game simulate the employees of Hackers Inc., which is a tech security company that performs advanced checks on the security of individuals by actively trying to hack it and then provide consultation services to the individual on whom to improve their security. For the evaluation of the game, a group of 22 educators and 250 students were taking into account. Most of the educators indicated that the game was a great teaching tool, in that they would use it again, as it was greatly welcomed and enjoyed by the students, while it significantly increased their understanding of computer security. Therefore, some educators believed that they would even recommend it to others. A secondary supplementary evaluation of 11 educators teaching nonsecurity computer science courses showed that their response similarly aligned with a larger group, with some reporting that they would no longer teach any computer science course with the game.

Conclusion

In this article, the authors discussed and referenced briefly phishing attacks focusing on gamification which is actually social engineering. Then they categorized the existing strategies to tackle the issue and enhance the awareness of users regarding the gamification solutions. Phishing manipulates individuals psychologically to reveal confidential information. Phishing is a common form of identity theft and is considered a serious and server cybercrime. The most common phishing uses emails, chats or websites, and online games to get valuable information. Education and training in the case of gaming have become very essential even for a common man to prevent phishing. In order to handle phishing in gaming, some of the existing methods have been discussed. Since organizations are emphasizing the education and training of their employees for data protection, game-based learning is one of the top methods to identify phishing attacks.

AOI; Area of interest

Definition

In a Massively Multiplayer Online Game, the Area-Of-Interest (AOI) is that portion of the virtual world of specific interest for a player.

Introduction

Users participating in a Massively Multiplayer Online Game (MMOG) share a synchronous and persistent virtual world with each other through Avatars, i.e., the players alter ego in the virtual world. In order to enable an engaging experience

typical of MMOG, the state of entities in the virtual world, such as avatars and objects, has to be replicated in avatar nodes in a timely fashion. However, broadcasting all state changes to every node in a MMOG is not a practical solution. Naturally, each avatar is interested to be updated in only a subset of the whole virtual world, which is commonly referred to as Area of Interest (AOI). The AOI management (AOIM), often referred to also as Interest Management (2002), is a core activity in the operations of a MMOG, and can be informally defined as the following: given an avatar, identify its AOI and activate those operations that support its timely update. AOIM is also referred to as spatial publish subscribe (Hu and Chen 2011). In this model, publishers perform action and interact with the virtual world (e.g., perform some movements), whilst subscribers manifest their interest of receiving updates for a specific area of the virtual world. AOIM is a fundamental operation in both centralized and distributed MMOG architecture. In the centralized ones, it is principally a mean to reduce the volume of messages exchanged by the client and the server, as well as the amount of data stored and elaborated locally to the client. In distributed MMOG architectures instead, how AOIM is performed greatly impacts on the whole architecture. In fact, AOIM often drives the design of the whole decentralized architecture, forcing an organization of the connections between nodes so that they are only communicating with other nodes that have relevant entities. AOIM can be divided into two main categories (Carter et al. 2012): spatial and geographic.

Spatial AOIM

Spatial AOIM is based on the concepts of aura and nimbus (Boulanger et al. 2006). The aura is the spatial area for which an entity is perceived by others, whilst the nimbus is the spatial area for which an entity can perceive. Hence, an entity A can perceive another entity B only if A's nimbus intersects with B's aura. However, in this case, B is not necessarily aware of A (i.e., the relation is not mutual). In practical implementations, however, aura and nimbus coincide in a circle (or a sphere) with a predefined radius and centered on the avatar. In such case, the circle is simple referred to as AOI, and the awareness is mutual such that if A is aware of B, B is also aware of A. Spatial-based AOIM mechanisms can employ a static and persistent implementation of the AOIs (Carlini et al. 2012), or dynamic, by adjusting the AOI shape and size according to the events happening in the virtual world (Ahmed and Shirmohammadi 2008).

Geographic AOIM

Geographical AOIM exploits the subdivision of the virtual world into regions, which are then distributed to different servers. Geographical and spatial AOIM are often used in combination: the spatial AOIM is used to select those, among the regions provided by the geographical AOIM, that are of interest for the avatars. A coarse grained geographical AOIM is usually implemented by large centralized MMOG by dividing the virtual world into large regions and instances (Prodan and Nae 2009). Normally, the nimbus of avatars is much smaller than such regions, and therefore only one region (i.e., server) is selected, as typical of centralized approaches.

More fine grained subdivisions of the virtual world are typical of decentralized MMOG architectures (Ricci and Carlini 2012). A common approach considers an uniform partitioning of the virtual world into rectangles or hexagons, with the area of interest that can span more regions. Static uniform partitioning approaches have the problem of properly defining the region size. If the size is too large, an avatar could receive state updates from entities not in its actual interest, wasting resources. Otherwise, if the region is too small, an avatar would need to manage multiple region of interests and switch very frequently between them, generating a lot of overhead. In order to overcome these problems, in dynamic partitioning, the size of the region can be optimized according to various parameters, such as the number of avatars in a region, or the computational power of the node managing a region (Deng and Lau 2014). An evolution of the dynamic partitioning approach is the hierarchical partitioning, which is usually implemented by considering tree-like structures, such as QuadTrees (Backhaus and Krause 2010). An advantage of this method is that the size of the

regions can be abstracted at the correct level by simply navigating the tree structure. A special instance of geographical AOIM is the one based on Voronoi tessellation (Hu et al. 2006). A Voronoi tessellation is a decomposition of a metric space determined by the distances from a set of sites (usually determined by the position of the Avatar) of a discrete set of objects in the space. Given a set of N sites on a two-dimensional euclidean plane, the plane is partitioned into N nonoverlapping regions, each one containing all the points closer to that region site than to any other one. Voronoi-based AOIM approaches, and the corresponding Delaunay triangulation (Ricci et al. 2015), are especially used in decentralized MMOG architectures as they facilitate the task of connecting neighbors with P2P mechanisms. In general, the Voronoi tessellation is dynamically computed by considering the positions of the avatars, then a peer-to-peer communication overlay is defined by connecting two peers managing avatars whose Voronoi regions share at least an edge (i.e., are neighbors) (Ricci et al. 2013).

Synonms

Augmented reality; Extended reality spectrum

Definition

The Artificial Reality Continuum (ARC) describes the spectrum of technologies that augment or replace the natural sensory stimuli: vision, hearing, touch, smell, or taste. On one side of the spectrum is the reality itself, as perceived with our own senses without artificial augmentation. On the other side of the spectrum is the virtual reality, where sensory stimuli are entirely artificially generated. In between the reality and virtual reality, the degree of augmentation, extension, or replacement of natural sensory stimuli varies.

Introduction

The ARC is always tied to a human user Scholz and Smith (2016); Dirin and Laine (2018). It cannot exist without a human being because it is just an experience. It is possible for many humans to view and interact with the same artificial reality (Kaufmann (2003); Pidel and Ackermann (2020)). Recently, collaborative artificial reality applications are commonly referred to as the *Metaverse* Mystakidis (2022). Generally, the artificial reality continuum is a virtual concept and is experienced through the visual sense of a human. Besides vision, the hearing sense also plays a secondary important role. Through sound, the level of immersiveness of the artificial reality experience is increased. In some cases, the visual artificial reality gets extended and stimulates the other human senses touch, taste, and smell.

The disciples in the ARC are Augmented Reality, Mixed Reality, and Virtual Reality. It is also important to define the boundaries of the ARC. An important factor is the degree of visual immersiveness and interaction with the environment. A traditional theater experience can be physiologically immersive. People's emotion change because they feel with the characters. Yet, the acting takes place in reality and is therefore not considered artificial reality. Sitting and watching in a movie theater can be immersive, and the reality that is shown on the screen is artificial, but still this is not considered artificial reality because there is no active interaction between the movie and the environment the viewer is in.

The ARC was defined from a device perspective by Milgram et al. (1994). They create a taxonomy that divides the ARC in three dimensions: reality, immersion, and directness. The three axes refer to the extent of world knowledge, reproduction fidelity, and extent of presence metaphor. Skarbez et al. (2021) adapted the taxonomy by Milgram et al. (1994) and introduced the three dimensions' extent of world knowledge, immersion, and coherence. This work analyses the ARC from a user experience and application perspective focusing on current technological capabilities with current devices. Moreover, we define Mixed

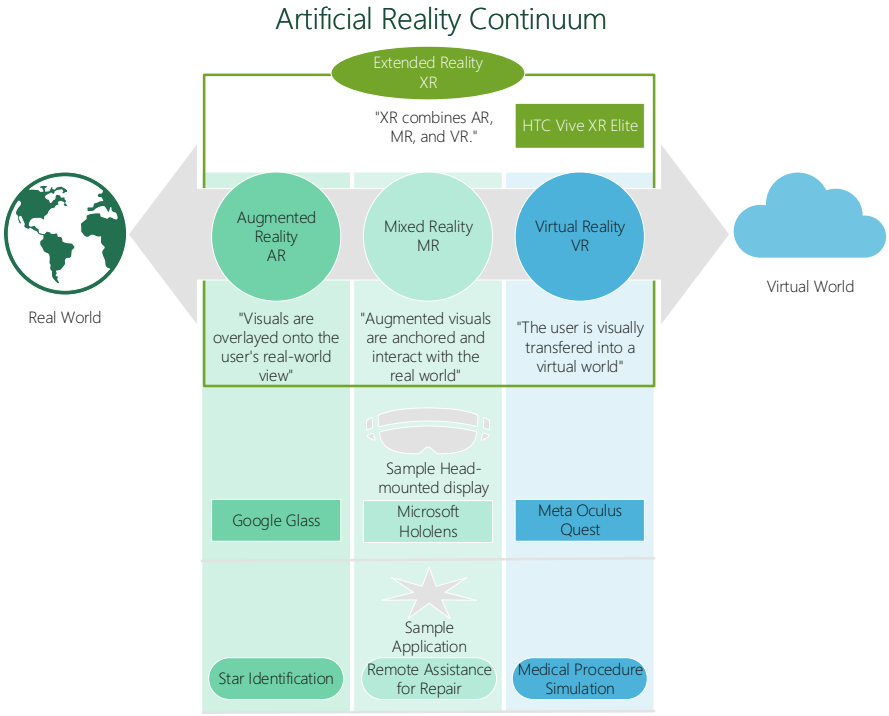
Reality (MR) as a stage between Augmented Reality (AR) and Virtual Reality (VR) rather than an umbrella term describing the whole spectrum. Instead, Extended Reality (XR) includes AR, MR, and VR. An overview of how the ARC is presented in this work is shown in Fig. 1.

Disciplines Within the Artificial Reality Continuum

People start to talk about the artificial reality continuum as soon as the information that is visually displayed depends on the environment the user is in. In all forms of artificial reality, the awareness between virtual and reality goes only in one direction. From the real environment to the virtual environment. The interaction can never happen in the opposite direction because this would mean that reality changes directly from the influence of the virtual reality (VR) which is physically not possible. However, the user can act as a bridge between virtual and real environment. Indirectly the virtual environment can influence the real environment. For example, the virtual environment can tell the user how to perform a certain operation in the real environment. Examples include remote maintenance (Mourtzis et al. 2020), and health-care assistance (Rebol et al. 2022). Once the user performed the instructions visualized in the virtual environment, they indirectly changed the real environment.

Augmented Reality

In augmented reality (AR), the information flow between the virtual and the real environment goes only from the real to the virtual environment. The real environment gets extended with visual and auditory information (Reipschlager et al. 2021). In some AR applications, the physical environment influences how the virtual world is rendered. However, this is not a requirement for AR. Some AR applications scan the physical environment to provide anchored augmentations depending on which real environment the user sees. This allows for predefined visualizations to get displayed on



Artificial Reality Continuum, Fig. 1 An overview of the Artificial Reality Continuum (ARC)

top of reality. Augmented reality is not designed to change the real environment. The boundary between augmented reality and mixed reality is at the point where the augmented information tries to influence the real environment. The sole purpose of augmented reality is to enrich reality by providing additional visualizations.

In museums, AR is used to provide text descriptions and animations for exhibits (Ding et al. 2017). In books, AR is used to extend traditional 2D illustrations with 3D AR scenes (Dünser et al. 2012). Interactivity does not take place with the AR objects itself. Only small changes in the virtual environment are possible such as changing the position where the virtual elements appear. Pokemon Go pok (2022) is the most famous AR game. Besides the entertainment applications, AR is also used in heads-up displays in air crafts and vehicles (Jose et al. 2016). The virtual elements in the game (Pokemon) appear augmented through a screen on the real world. Augmented reality devices are displays of phones and tables, projectors, and glasses with integrated see-through displays.

Mixed Reality

In contrast to augmented reality, mixed reality (MR) not only enriches the real environment by displaying visualizations for the user but also makes the user interact with the environment. The virtual environment changes the real environment with the help of the user. The interaction must include the physical environment and can also take place in the virtual world. MR headsets that support hand tracking allow the user to intuitively alter the virtual world. Moreover, in every mixed reality application the virtual environment is fully aware of the real environment. Mixed reality is the most complex technology because it tries to create a new seamlessly combined reality. In AR, the attention is on the real environment and the augmentations just enrich the reality. In virtual reality, the attention is on the virtual environment and the user is not visually aware of the real environment. In MR, the attention switches between the real and the virtual environment.

Mixed reality creates a cooperative scene which can be used for virtual meetings and collaboration. Virtual objects are used to explain concepts in the real environment. One person can guide another person if the mixed reality views are transferred over the Internet (Rebol et al. (2022); Mourtzis et al. (2020)). One person can give direction using virtual objects on the other side. The person that receives the direction through mixed reality can work based on the directions received. In industries, mixed reality is often used in cases where a remote expert guides a local operator (Rebol et al. 2022). Traditional 2D video guidance is sometimes not practical because the complexity of the problem requires spatial information. In the logistics industry, special machines are deployed in warehouses (Mourtzis et al. 2020). Only few experts are able to fix the machines whenever they stop working. In order to repair machines efficiently, a remote expert guides a local mechanic through the procedure with MR. The remote expert would otherwise need to travel long distances to fix the problem which would take more time and cost would be high.

Virtual Reality

Virtual reality (VR) tries to completely detach the user from reality and take the user to an all virtual environment (Auda et al. 2020). Although the user keeps physically in the real world, virtual reality creates the impression that the user enters a new virtual world. Compared to augmented and mixed reality, the user does not see anything from the real environment, except for themselves in cave automatic virtual environment (CAVE) experiences (Muhanna 2015). Most of the time, the visual experience is also paired with audio and the user wears headphones which makes the user hear sounds from the virtual environment. Modern virtual reality devices are displays mounted very close to the user's eyes to cover the real environment. They are head-mounted displays (HMDs) consisting of the display, headphones, microphone, and sensors to track the user's motion. In order to make the virtual experience of Artificial Reality Continuum 5 as realistic as possible, the motion of the user is tracked and transferred to motion in the virtual environment. VR device tracking ranges from head tracking only to full body tracking.

Similar to mixed reality, virtual reality is used for virtual meetings and collaboration. Distant people can meet in the virtual world to discuss work in the real world or work together on virtual tasks. People see each other as represented as avatars in the VR. The degree of avatar detail and realism changes. The degree of avatar realism has an influence on the perception in VR Latoschik et al. (2017). More abstract avatar representations require less computing power. Realistic representations can be retrieved by a volumetric capture of a person (Yu et al. 2021). However, in combination with realistic capture, precise motion tracking and mesh deformations are required to reach a high degree of realism.

One difference between virtual reality and augmented and mixed reality is the fact that it is completely detached from the real environment. Therefore, the user can be taken into a completely new world which the user would not be able to experience in reality. It can be a place on real world that is somehow unreachable for the user such as the cockpit of a rocket or distant vacation destination. It can also be a completely fantasy place. This allows for the application to simulate situations and train people. Examples include fire rescue, medical training, and pilot training. By combining a visual VR experience with additional realism such as sound, haptic feedback, environment motion, and smell, a highly realistic scene is created. The user's body is physically moved according to the visual VR experience.

The Continuum

The transition between AR and MR is seamless. MR applications include AR. AR and MR can be distinguished by the sensors the display device is using. In AR, there exist two types of augmentation. The most simple version of AR augments information onto a display without taking the real environment into account. One example for this is a heads-up display in a car that projects cruising information such as speed and direction onto the windshield (Jose et al. 2016). Another example would be wearable see-through glasses that project the current time and weather information into the field of sight of the user. This information is projected regardless of the environment the user is currently in. Those devices only need a projecting display. They do not need sensor to scan the environment.

The more sophisticated version of AR is partially aware of its environment. This version of AR scans the environment and searches for predefined elements on which information is augmented. For example, in an AR book (Dünser et al. 2012), the AR device is searched for illustrations or markers. Whenever something is detected, the corresponding visual information is overlaid for the user. This detection requires additional sensors for the AR device. Mostly, these types of AR devices contain a display and a color camera. Devices are mainly phones, tablets, and glasses. The color camera captures the real scene and applies image recognition algorithms to detect given objects in the scene. Consequently, these types of AR devices require more computations resources compared to the most simple form of AR. Despite recognition, tracking is performed to stabilize augmentations when the user moves the AR device. The tracking makes this type of AR more enjoyable than simple AR displays. It makes the virtual and the real environment merge and the experience for the user is better because the user does not need to switch visually between the decoupled virtual and real environment. Accurate tracking is an important factor for a smooth AR experience. Slow or inaccurate tracking results in high cognitive load for the user and can result in motion sickness (Kaufeld et al. 2022).

Mixed reality is very closely related to the more sophisticated version of AR described above. The main difference is that in mixed reality the awareness of the real environment is even higher when creating the virtual environment. Therefore, MR devices have more sensors than AR devices. They spatially capture the surroundings the user is in. A depth sensor, a stereo camera setup, or laser-based systems are used to capture the 3D scene. In order to process this information, more computations resources are required compared to AR devices. Typical MR devices include phones which 3D capture capabilities and head-mounted displays.

In MR, device tracking becomes an important part because all the virtual objects are linked to the

real objects and need to stay at the same position. On head-mounted displays, the motion of the user's head needs to be tracked (Sathyanarayana et al. 2020). On phones, the position of the device needs to be tracked. Especially with head-mounted displays presenting a high portion of virtual environment, motion sickness (Kaufeld et al. 2022) becomes a concern, and therefore accurate head-tracking becomes essential. Even with a low degree of virtual environment, head-tracking needs to be accurate in order to decrease cognitive load and to support seamless integration of the virtual and the real environment. To allow for accurate tracking of user motion, the data from multiple sensors inside the MR device are utilized, including depth sensors, multiple RGB cameras, accelerometer, and gyroscope.

Mixed reality applications typically do contain AR elements that are not aware of the real environment and are visualized on a fixed screen position. These elements are typically application menus that are used frequently by the user and therefore need to be close. Mixed reality applications have the option to guide the user to engage not only with the virtual environment, but also with the real environment. Thus, MR is the preferred discipline within the artificial reality continuum for effective remote collaboration.

Although MR applications with a high portion of virtual elements come close the virtual reality experience, the concept of VR is substantially different from that of AR and MR. The user drifts completely into the virtual world. VR devices are designed such that they block the sight of the real environment. VR is predominantly consumed with a head-mounted display which blocks any light coming from the real environment to the user's eyes. A very high immersiveness factor within the artificial reality continuum is reached when VR does not only use the visual sense to bring the user into the virtual world. The real environment might react corresponding to the virtual environment to simulate motion and touch.

Applications of Artificial Reality

The artificial reality continuum is present in video games as well as other applications (Das et al. (2017); Solbiati et al. (2020)). The most famous AR Game is Pokemon Go. The most popular AR application outside gaming is the heads-up display in cars. Mixed reality applications are not widely spread. They are mainly used for commercial and research purposes (Rebol et al. 2022). MR is used for remote assistance, for example, special machine maintenance (Mourtzis et al. 2020). It is also used in medicine for 3D visualization of recorded volumetric data on patients. Virtual reality is much more popular than MR. Especially the gaming industry uses VR head-mounted displays to create immersive gaming experiences. The movie industry has produced documentaries in VR.

One obstacle toward the broader adoption of the ARC is the lack of standardization of devices. AR, MR, and VR devices are designed with different sensors and capabilities which makes cross-platform development difficult. Standardized application development between different mobile devices, head-mounted displays, and other ARC devices needs to be introduced. The type of sensors on devices needs to provide standardized capabilities such as device tracking and remote connection.

Interaction in the Artificial Reality Continuum

The interaction with the ARC depends on the device. Modern mobile devices including phones and tables offer interaction with AR capabilities. They 3D scan the environment with a multi-camera setup and support AR and MR applications. Phone displays offer low-entry VR support with additional head-mounted hardware. AR applications for mobile phones are popular because of the wide availability of the hardware. The fact that the display needs to be carried makes mobile phones a less suitable device for ARC applications. Moreover, state-of-the-art phones do not offer stereoscopic display capabilities. Consequently, only 2D views are supported.

In contrast to phones, glasses and lenses offer 3D visualization and are easier to carry. The

display and the computing unit need to be separated on these devices for comfortable usage. Glasses and lenses offer a much more intuitive way of consuming ARC content. When using mobile device, the interaction can happen through traditional touchscreen controls but can also happen through more intuitive in-the-air gestures. Gestures are detected using integrated hand pose estimation algorithms which are less accurate than touchscreen controls. On head-mounted displays, interaction is possible with gestures. Integrated depth cameras can ensure high precision such that the interaction with virtual objects feels similar to interaction with physical objects.

Within the ARC, augmented reality does not support interaction. Mixed reality applications require spatial scene understanding to allow for interaction with both physical and virtual objects in a natural way. Natural interaction happens through user gesture control. Hence, gesture detection is built in. In VR, gestures are detected with controllers or stereo cameras. Besides gestures, voice recognition is used for communication in a virtual environment. The disadvantage of gesture recognition with controllers is that the user has to hold a physical object which is less natural than gesture recognition with cameras. Gesture recognition with separate static hand-tracking devices is feasible put limits the area of interaction and is therefore mainly suitable for VR.

Conclusion

The artificial reality continuum offers different ways for the user to interact with virtual content: augmented reality, mixed reality, and virtual reality. Current consumer products come from both ends of the spectrum which are augmented reality and virtual reality. Especially for productivity and collaboration, mixed reality plays an important role. It is widely adopted in industry and is on the way to enter consumer markets.

Head-mounted displays combined with human user tracking offer the most intuitive technology to experience the artificial reality continuum. In the future head-mounted devices will have to become handier and part of people's everyday life.

Artistic Data Visualization in the Making

Rebecca Ruige Xu
Syracuse University, Syracuse, NY, USA

Synonyms

Artistic visualization; Data visualization

Definition

Artistic data visualization is visualization of data done by artists with the intent of expressing a point of view.

Introduction

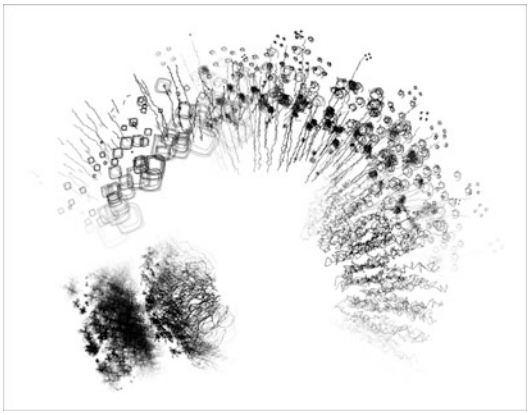
In recent years, we have seen an increasing of interest in data visualization in the artistic community. Many data-oriented artworks use sophisticated visualization techniques to express point of views or achieve persuasive goals. Meanwhile the attitude that visualizations can be used to persuade as well as analyze has been embraced by more people in the information visualization community.

Here I will share my experience and reflection in creating data visualization as artwork via case study of two recent projects. It presents a workflow from conceptual development, data analysis, to algorithm development, procedural modeling, and then final image production. It hopes to offer insight into the artist's effort of finding balance between persuasive goals and

analytic tasks. Furthermore, it raises the question of the roles of artistic data visualization played in assisting people to comprehend data and the influence of this artistic exploration in visualization might have injected in shifting public opinions.

Case Study: Out of Statistics: Beyond Legal

This project produces a series of 52 abstract drawings based on US crime statistics as digital prints on rice paper and silk panels. Each image represents the crime status in one of the states, with the seven most significant crime-conviction statistics of each state embedded.

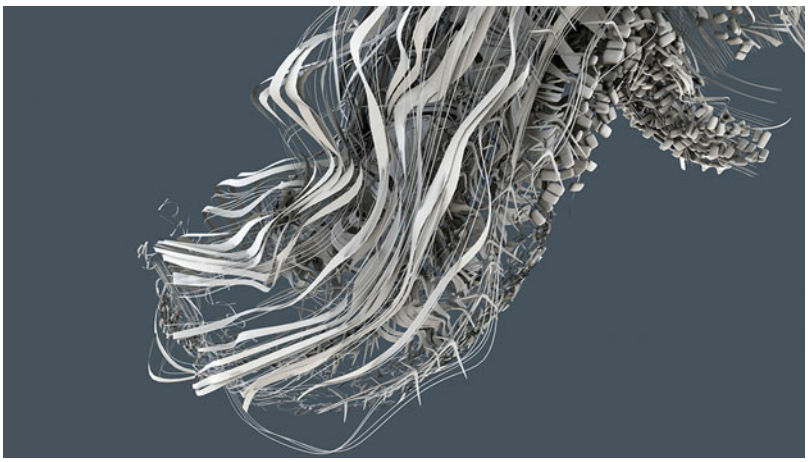


Case Study: Perpetual Flow

This project explores an aesthetic-oriented approach to visualizing federal spending in the United States as 3D compositions in a photo-realistic style. Using procedural modeling with Python programming and Maya API, an organic flow of intermingled geometrical units is formed to represent the profile of federal spending for each state, loosely resembling the idea of money flow. The total amount of spending is scaled to a per capita basis to make different states comparable, while the overall surface area or volume occupied by each type of geometrical pattern represents its associated spending data (Xu and Zhai 2013).

Biography

Rebecca Ruige Xu currently teaches computer art and animation as an Associate Professor in College of Visual and Performing Arts at Syracuse University. Her artwork and research interests include experimental animation, visual music, artistic data visualization, interactive installations, digital performance, and virtual reality. Her recent work has been appeared at Ars Electronica; SIGGRAPH Art Gallery; Museum



of Contemporary Art, Italy; Aesthetica Short Film Festival, UK; CYNETart, Germany; International Digital Art Exhibition, China; Los Angeles Center for Digital Art; Boston Cyberarts Festival. She has also been a research fellow at Transactional Records Access Clearinghouse, Syracuse University since 2011.

Action-adventure game; AnvilNext; Artificial intelligence agent; Assassin's Creed

Definition

Action-adventure game	A game with a mix of elements from an action game and an adventure game
Action game	A game that requires physical skills and challenges such as hand–eye coordination and reaction time
Adventure game	An interactive story driven by exploration, dialogues, and puzzle-solving
Artificial intelligence agent	An automated agent that performs tasks by mimicking some levels of human intelligence
AnvilNext	A game engine created in 2007 by Ubisoft Montreal video game developers for use on Microsoft Windows, Nintendo Switch, PlayStation 3, PlayStation 4, PlayStation Vita, Wii U, Xbox 360, and Xbox One

Abstract

Assassin's Creed is an action-adventure video game franchise created by Patrice Désilets, Jade Raymond, and Corey May, developed and published by Ubisoft using the game engine AnvilNext. Coded mainly in C++ and C#, Anvil is a game engine created in 2007 by Ubisoft Montreal for use on Microsoft Windows, Nintendo Switch, PlayStation 3, PlayStation 4, PlayStation Vita, Wii U, Xbox 360, and Xbox One.

Assassin's Creed IV: Black Flag

Have you even wondered what it would be like to be a pirate in the middle of the Caribbean during the height of pirating? Well, look no further than the awesome sequel to the Assassin's Creed Series: Assassin's Creed IV – Black Flag. The Ubisoft company, specifically the Ubisoft Montreal office, made every effort to make sure this game was a blockbuster on its release back on the 29 October of 2013, to include utilizing the advanced AnvilNext Engine for the Xbox 360 release. The game was during its time one of the most advanced action-adventure/stealth games of that year with an initial

release on Xbox 360, PlayStation 3, and Wii U; it was later patched over to the PlayStation 4, Xbox One, and Microsoft Windows after the release of the next-gen consoles on 22 November 2013. This gory single-player/multiplayer will have you sitting on the edge of your seat, taking full advantage of the ESRB rating of M for Mature.

The game's main target audience was young adults between the ages of 18 and 25. The story was an easy hook for people who are fans of the series or not. Being a ship hand named Edward Kenway during the 1700s in the Caribbean who turns pirate to earn fortune has a brief run in with an assassin captain of an enemy vessel, whom Edward kills and steals his gear to impersonate a captain of a ship without realizing the uniform has other ties besides just the title of "Captain." With the gear he is consistently being pursued by an organization called the Templars who are seeking a device in the Caribbean and the Assassin's Brotherhood who seek him out for assistance in stopping the Templars. This game is so appealing not just due to the awesome aspects of pirating but also due to doing it during the greatest age of pirating! Plus, this series has a long working story arc over many games when it comes to the "present-day" story portion.

Games Mechanics

The games mechanics were unique even for this series. Each game in the Assassin's Creed franchise has brought a little something new to improve on the previous game, but they are usually minor like a slight adjustment to the combat mechanics or the ability to parkour (wall climb) up and down with a simplified button combo than in the previous game. In Black Flag however, they broke the mold of Assassin's Creed.

Assassin's Creed has been well known since the first game for its large landscapes, big maps, and the use of the parkour system to navigate the map in literally three dimensions. With that said, Black Flag had the largest map ranging everywhere south of the tip of Florida to Jamaica as shown in the following picture:

With this large map, most players would be daunted to think about the number of load screens that would have to go through every time they made a move toward one place or the other. The load time is a little above average, with approximately a 1–2 min load screen just to get into the game, but once you are in, you are in a completely open world with only two exceptions. The first being story cut scenes which is a given, but they flow well and do not have a load screen to prompt them. The other being the quintessential "Fast Travel" locations in game, which do have a load screen, but it is dramatically reduced compared to the opening screen, with only about a 30 s load time.

If you are thinking a map this large, surely, you would speed all your time just using the fast travel points to get around. Wrong! You have a ship that can travel around this area at a reasonably quick pace. You can go from "driving" to "walking around" in character at a push of a button. The fluid ship to person back to ship interaction makes it really easy to travel because all you have to do is pull up next to an island you wish to visit, stop driving the ship, and just jump off the side to swim ashore (again no loading screen for visiting a new location in the map).

Artificial Intelligence Agent

Ubisoft did this mechanic due to another feature that they added into the game: a literal never-ending number of AI NPC ships that you can attack and loot or even take over by engaging in hand-to-hand combat while boarding the ship. These AI ships range from smaller ships which are easy to take out for the early game play to four "God" ships in hidden locations spread around the map which are near impossible to defeat unless you have your ship fully rigged with the best gear.

Storyline

The story is extremely in depth, with plenty of actual real-world locations to explore and dozens of historical figures from the Golden Age of Piracy to interact with. An example is Edward Teach who is better known as "Black Beard," the notorious English pirate who was a scourge of the American coast for many years before his death at the hands of sailors sponsored by the Governor of Virginia to capture or kill the pirate. Other big names from the day are Anne Bonny, Charles Vane, John Rackham better known as Calico Jack, and Benjamin Hornigold – all of whom are notorious pirates from that time.

Assassin's Creed IV: Black Flag's open-world concept with a free-flowing story and the option to ignore the story and just do pirating stuff has received great public reception and was generally held as vastly superior to its predecessor Assassin's Creed III. Two days after the game's release, IGN ranked Assassin's Creed IV: Black Flag as the second best game in the Assassin's Creed series, only behind Assassin's Creed II (Sliva 2013).

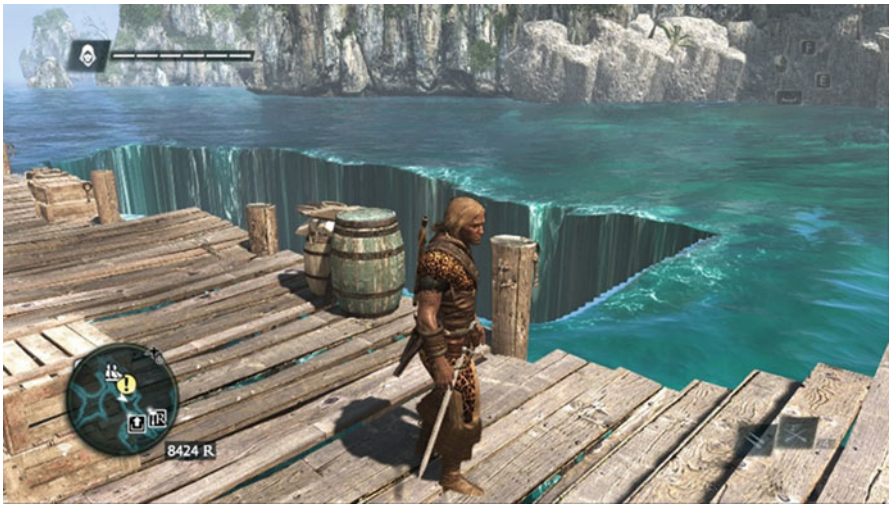
This game is perhaps the best game in the series by far. It has all the best features of the series with double story, open range action/adventure gameplay, and the awesome aspect of interacting with some of history's biggest names during the Golden Era of Pirates.

Controversy

The only controversy that popped up for this game is that PETA, the People for the Ethical Treatment of Animals, criticized the game for its usage of harpoons and the glorification of whaling. PETA also came out and said that it was disgraceful that the video game industry did not condemn it. Ubisoft's response was a statement saying that Assassin's Creed is based on history and it is a "work of fiction which depicts real events during the Golden Era of Pirates." Ubisoft also claimed they do not condone whaling, along with other mechanics and features in the fourth game in the series as shown in the following pictures:

Criticisms

The game was released only a month prior to a new generation of consoles coming out, and therefore it was built using an engine for the older generation of consoles (Xbox 360, PlayStation 3). When it was ported over to the new consoles (Xbox One, PlayStation 4), Ubisoft did not optimize the game for the better hardware in the newer



Assassin's Creed, an Analysis, Fig. 1 In the image, the large "hole" in the water is actually the player's ship resting in the water, but it is invisible to the player due to a software bug caused by the newer hardware

Assassin's Creed, an Analysis, Fig. 2 Assassin's Creed was released in 2007. You play as Desmond Miles in the modern story and as Altaïr Ibn-La'Ahad who lives during the Third Crusade in multiple locations in and around Jerusalem

consoles. As a result, many glitches happened when attempting to play the game on the newer consoles. In the image above, the large "hole" in the water is actually the player's ship resting in the water, but it is invisible to the player due to a software bug caused by the newer hardware.

Another major complaint from the gaming community is about the annual release of a new game. Ubisoft has been criticized for causing an oversaturation of the genre and a loss of innovation for the story arcs in each game.

Assassin's Creed, an Analysis, Fig. 3 Assassin's Creed II was released in 2009. You play as Desmond Miles again and as Ezio Auditore da Firenze during 1476–1499 centered around Florence, Italy

Assassin's Creed, an Analysis, Fig. 4 Assassin's Creed Brotherhood was released in 2010. You play as Desmond Miles again and as Ezio Auditore da Firenze during 1499–1507 centered around Rome, Italy

Evolution

The changes in each game in the series over the years have been minor. Comparing to the first Assassin's Creed on Xbox One S, the nine sequels to Assassin's Creed offer only minor improvements in graphics and audio.

The following series of pictures showcases the evolution from 2007 to 2018:

Assassin's Creed, an Analysis, Fig. 5 Assassin's Creed Revelations was released in 2011. You play as Desmond Miles again and as Ezio Auditore da Firenze during 1511–1512 Constantinople, Istanbul

Assassin's Creed, an Analysis, Fig. 6 Assassin's Creed III was released in 2012. You play as Desmond Miles again and as Ratonhnhakén:ton also known as Connor Kenway, who is a Native American turned assassin during the American Revolutionary War between the years 1765 and 1777

Assassin's Creed, an Analysis, Fig. 7 Assassin's Creed IV: Black Flag was released in 2013. You play as an unnamed employee of the company Abstergo during the modern story and as Edward Kenway during the Golden Era of Piracy between 1715 and 1722 in the Caribbean

Assassin's Creed, an Analysis, Fig. 8 Assassin's Creed Rouge released in 2014 was the final game designed for the Xbox 360 and PlayStation 3 generation of consoles but was later given a remastered edition for the new generation of consoles. You play as an unnamed Abstergo employee and as Shay Patrick Cormac who is an Assassin turned into a Templar (the assassin's rivals) during the 7 Years' War from 1756 to 1776 in the British colonies of North America

Assassin's Creed, an Analysis, Fig. 9 Assassin's Creed Unity released in 2014 was the first Assassin's Creed game created and released only for the new generation of consoles. It was also the first to incorporate a cooperative multiplayer in the story. You play as the "Initiate" who is a player of the Abstergo game called "Helix" and as Arno Dorian who is an assassin during the French 252 Revolution in 1789 and who goes to the Thermidorian Reaction in 1794 in Paris, France

Assassin's Creed, an Analysis, Fig. 10 Assassin's Creed Syndicate released in 2015 is the first Assassin's Creed to include two main characters that are played simultaneously in the memory segments of the gameplay to include the series' first playable female character. You play as the "Initiate" who has fully bought into the Assassin Brotherhood and is working for them in the present time, and during the past, you play as twins Jacob and Evie Frye during 1868 Victorian Era London, England

Assassin's Creed, an Analysis, Fig. 11 Assassin's Creed Origins was released in 2017. You play as Layla Hassan, a researcher at Abstergo's Historical Research Division during the present-day story, and as a Medjay named Bayek during 49–43 BC Ptolemaic, Egypt

Assassin's Creed, an Analysis, Fig. 12 Assassin's Creed Odyssey was released in 2018. The game takes place in Ancient Greece in the year 431 BCE during the fic tional Peloponnesian War between Athens and Sparta. You play as a male or female mercenary who fights for both sides

References

For a game series that spans 11 games between 2007 and 2018 for various gaming platforms, there are countless articles, magazines, blog posts, and online articles that talk excessively about this series: from IGN to The Game Informer Magazine published by Game Stop. This series has been in the spotlight and is still going strong in spite of the "dark times" of the original Assassin's Creed and the failure of Assassin's Creed Unity due to rushed game development. This game series continues to be at the forefront of the RPG arena due to extraordinary writing and storylines along with above average graphics and annual title releases from Ubisoft. Definitions

CAPTCHA (Completely Automated Public Turing test to tell Computers and Humans Apart) is a security check software placed on websites as a means to allow to differentiate users from bots upon login (Jiang and Dogan 2015). Security is needed to ensure that bots cannot enter protected environments, such as those associated with games or purchases, in order to protect human users and companies alike from the impact of unwanted interference of all kinds, including financial, social, or otherwise (Fanelle et al. 2020). Accessibility is a measure of equity in access to sites and site information for people with a range of disabilities (Berton et al. 2020). The article refers to visually impaired users as inclusive of both legally blind users as well as those who have sight differences or deficiencies that prevent their equitable use of sites and site information.

Introduction

Because bots exist, there will always be a need for processes to protect sites and users from their interference (Fanelle et al. 2020). Even so, visual impairments require the installation of alternatives to standard visual CAPTCHAs, which include character-based and audio-based options. At the same time, these alterative CAPTCHA designs may not be as effective, easy to use, or timely as standard visual CAPTCHAs, based on these viability requirements, and the fact that audio CAPTCHAs in particular are easily hacked (Meutzner et al. 2015). This means that CAPTCHAs for visually impaired users can lack both accessibility and security.

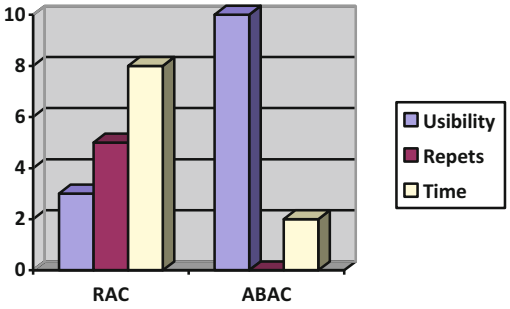
Our contributions in this paper are as the following:

- We have used advanced biometrics for facial recognition model in a real-time face detection.
- We proposed to use our impeded model for Webcam to improve the Audio CAPTCHAs.
- Finally, we are presenting the state-of-the-art accuracy for both facial recognition detection time and CAPTCHAs improvements for Visually Impaired Users.

Using Biometric for CAPTCHAS

The availability of alternatives to standard visual CAPTCHAs is limited. Biometric designs may be seen to be an easy solution to the issue (Noorjahan 2019), but the reality is that most visually impaired users engage in web-based sites through specialized equipment which may or may not be able to accommodate Fig. 1 provide some of the common equipment used for fingerprint, and they compared to the proposed method of using the actual key on the keyboard as an authenticated key. That would be as an option in the near term for using speech recognition instated of Audio CAPTCHAs (Fanelle et al. 2020). This means

Audio and Facial Recognition CAPTCHAs for Visually Impaired Users, Fig. 1 Type of biometrics is available for fingerprint



Audio and Facial Recognition CAPTCHAs for Visually Impaired Users, Fig. 2 Percentage of users for in the survey for each category of disability

Audio and Facial Recognition CAPTCHAs for Visually Impaired Users, Table 1 The characterized data of the participants were collected during our evaluation

Age	Number of participants	Visually impaired%
6–15	10	50
16–35	42	40
35+	11	80

that options that can take advantage of standard hardware, i.e., hardware that is used most frequently by visually impaired users, need to be prioritized (Alnfiai 2020). Whether standard hardware changes in the future or not, CAPTCHA options need to reflect what users prefer in order to meet accessibility and equity expectations (Berton et al. 2020).

Alternative CAPTCHAS for Visually Impaired Users

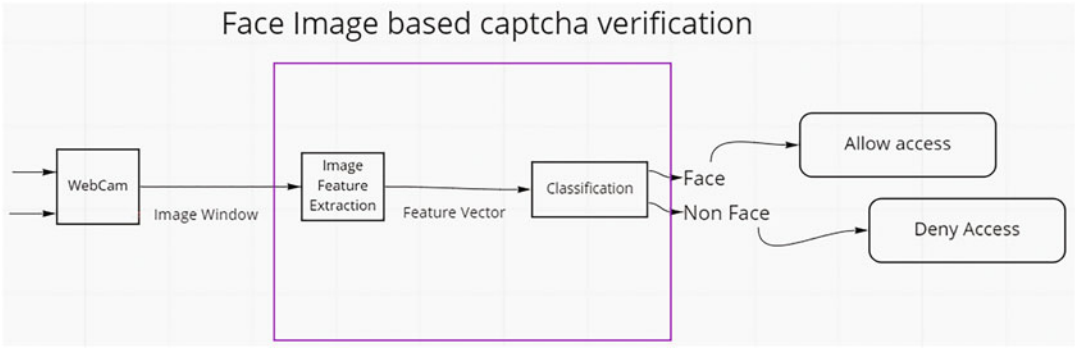
Given these needs, a number of alternative CAPTCHAs for visually impaired users have been tested in scholarly research in recent years and a number of factors that ought to be considered have been prioritized. The most ideal CAPTCHA is one that works for both sighted and visually impaired user with little to no differentiation, so that potential programming gaps are addressed (Alnfiai 2020; Shirali-Shahreza et al. 2013). This means that solutions need to be equally seamless for all users, and decrease extant time gaps for people with visual challenges (Alnfiai 2020; Fanelle et al. 2020). However, this is not always feasible, and most solutions need to work with existing web audio accessibility inputs such as Google reCAPTCHAs (Berton et al. 2020). CAPTCHAs that allow a user to swipe on a phone or handset when they hear a sound are likely to be successful (Alnfiai 2020). Having users reply using their own voices can be successful if security gaps are addressed by recombining CAPTCHA words in a control sequence that is connected with reCAPTCHA technologies (Jain et al. 2019).

Figure 2 shows the results of our comparison between Regular Audio CAPTCHAs (RAC) and our proposal Advanced Biometrics Audio CAPTCHA (ABAC). Table 1 presents overall data of the participants during the research.

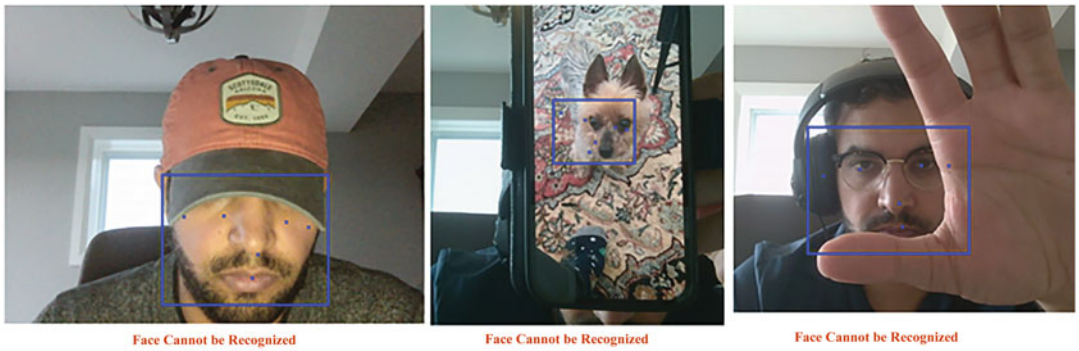
Our Proposal and Implementation

We currently use the deep learning-based facial recognition model called tiny face detection, built on the top of the single-shot shot detector (SSD) (Shafiee et al. 2017). Our deep learning model is made with the help of JavaScript programming, which helps us deploy the model over the web. After the model was built, we deployed the model over the web.

The main motive of our model is to detect if there is a human in front of the computer or not. So once the visually impaired person clicks the identify button, camera will open to determine if the person is present or not based on the facial recognition model. If a person is identified, then the captcha is a success and will go further if the camera fails to recognize the person. Then it says captcha is failed and ask's the user to try again. In



Audio and Facial Recognition CAPTCHAs for Visually Impaired Users, Fig. 3 Webcam model face recognition CAPTACHA



Audio and Facial Recognition CAPTCHAs for Visually Impaired Users, Fig. 4 Testing the accuracy of our model

Fig. 3 the architecture design for our proposed Webcam CAPTCHA.

This is the architecture of our deep learning model where initially, a person initiates the webcam, and then the feature extraction is done for every frame. Then it classifies whether based on the features extracted whether to allow or deny the access. The model will detect the face in a box for higher accuracy. Figure 4 shows defrent types of experiments we ran for testing our CAPTCHA.

Proposed Audio CAPTCHA Assistant

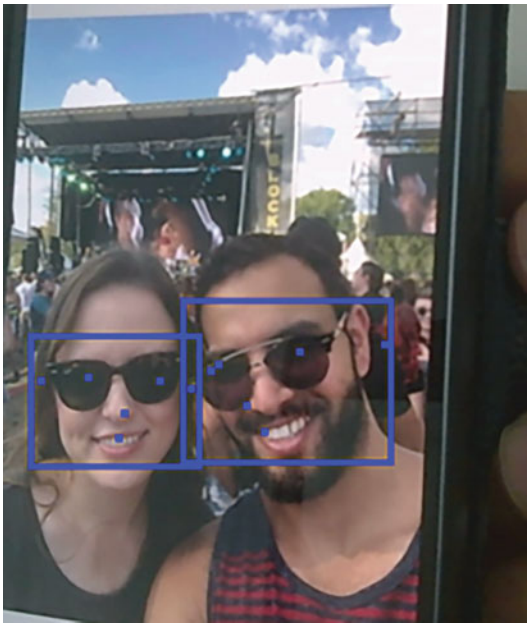
In our CAPTCHA, we have designed an audio assistant not only to provide speech to users but also provide guidance for visually impaired users. Instructions will be provided on how to best place the face for any visually impaired users on front of the webcam as shown in Fig. 4.

Limitations

There are certain limitations with our face detection model, such as our model is currently not able to distinguish between a photo and a normal person. In Fig. 5 the model will detect a face from picture where we intended to enhance the security to provide a real-time face detection with audio. The user will be able to hear the instructions for head adjustments, head rotation right, left, up, and down will eliminate any security issues we are facing from robots.

Conclusion and Future Work

For visually impaired users, alterative CAPTCHA designs may not be as effective, easy to use, or timely as standard visual CAPTCHAs. They may also lack security, especially if they are audio-based



Audio and Facial Recognition CAPTCHAs for Visually Impaired Users, Fig. 5 Our model detects the photo as a person and allows the captcha

alternatives. Nonetheless, new CAPTCHA options need to align to standard web protocols as well as standard hardware for visually impaired users and web browser accessibility requirements. This suggests that extra time is often the compromise that is made in designing CAPTCHA options that meet security and accessibility needs. Visually impaired users must spend extra time to get through a CAPTCHA sequence in comparison with standard users, which means that a truly equitable solution is lacking. Improvements to alternative CAPTCHA designs need to be created in order to ensure equity in the future, to avoid current pitfalls that create barriers to true security, accessibility, effectively and usability by introducing a real-time face detection CAPTCHAs.

Audiogame

Mikhail Fiadotau
Centre of Excellence in Media Innovation and Digital Culture (MEDIT), Tallinn University, Tallinn, Estonia

Synonyms

Audio game; Audio-only game

Definitions

An audiogame is a digital game that relies solely or primarily on audio output. Most audiogames can be played by both visually impaired and sighted players.

Introduction

While most digital games today heavily rely on sound in order to communicate information to the player, the role of audio in games is generally less significant than that of graphics (Collins and Kapralos 2012). Some digital games, however, invert this logic by either making graphics secondary to the audio or not using graphics at all, focusing on the sound instead. These are known as audiogames: games "fully playable by reliance on their audio output" (Karhulahti 2015).

For some game designers, stripping away the visual component of the game can be a way to experiment with the medium. *Dark Room Sex Game* (2008), a party rhythm game playable with the keyboard or Nintendo Wii's Wiimote controller, is one example, focusing on audio and haptic feedback to simulate sexual intercourse in a dark room (Oldenburg 2013).

More significant is audiogames' accessibility to visually impaired players, extending the reach of digital games beyond their traditionally assumed audience of sighted people (Friberg and Gärdenfors 2004). Online communities such as Audiogames.net have become hubs for visually impaired gamers, providing game reviews and publicizing events and competitions. The Game List section on Audiogames.net currently lists over 600 titles (most of them developed by hobbyists), though the list is not extensive and primarily focuses on English-language games.

History

Atari's *Touch Me* (1974), an arcade and handheld sequence memorization game, is considered to be a precursor to modern audiogames (Karhulahti 2015). While it did not exclusively rely on audio output (the sequence was duplicated as audio tones and light-emitted diodes lighting up), *Touch Me* could be played without using visual cues, although that would require the player to memorize the correspondence between the tones and the buttons first.

Audiogames for the personal computer became a possibility following the 1984 release of the original Apple Macintosh, which bundled with speech synthesis software *MacInTalk*. This enabled the Macintosh port of popular text adventure *Colossal Cave Adventure* to support voice output, making the game accessible to visually impaired users. Other text adventure games

followed, making the genre popular with the visually impaired gamer community.

The first notable commercial audiogame was *Real Sound: Kaze no Riguretto* (1997) developed by WARP Corp. for the Sega Saturn (Matsuo et al. 2016). It was conceived by game designer Kenji Eno after he learned of people with a visual disability who played his previous, visually intensive games by the ear. In terms of gameplay, *Real Sound* was an interactive radio drama where the player influenced the outcome of the story by choosing between several dialogue options at certain points within the game. While not a commercial success, *Real Sound* set an important precedent by being an audio-only game released by a major game publisher.

The 2010s have seen a rising number of audiogames appear: *Papa Sangre* (2010), *Sound Swallower* (2011), *The Nightjar* (2011), *Blindside* (2012), *Audio Defence: Zombie Arena* (2014), and many others (Beksa et al. 2015). The best-known of them, *Papa Sangre* (2010), is a survival horror game which takes place in a pitch-black dungeon, where sound positioning and reverberations provide the sole cues for navigation. Many contemporary audiogames, including *Papa Sangre*, are designed for tablets and smartphones; they also rely on touch controls, raising the question of their accessibility to players with a visual disability.

Some mobile audiogames, on the other hand, combine sound output with Braille writing to create a more accessible for visually impaired players while also helping them master Braille (Araújo et al. 2016). These games, however, may not be easily playable by sighted players who lack Braille literacy.

Design

On a basic level, there are several types of audio cues audiogames can rely on:

1. **Tone/pitch**: for example, Atari's *Touch Me* (1974) and *Simon* (1978), another memory game inspired by it, used sounds of a different pitch to identify the four key elements used to construct sequences for the player to memorize.
2. **Rhythm** and duration: rhythm games such as *PaRappa the Rapper* (1996) and *Beatmania* (1997) emphasize the timing of pressing the controls, and some subsequent games such as 2010's *Rock Band 3* can process actual music parts performed on a MIDI-enabled musical instrument.
3. **Spatial cues**: such games as *Papa Sangre* and *Blindside* focus on exploring invisible environments using sonic feedback such as reverberation.
4. **Narrative**: *Real Sound: Kaze no Riguretto* and the BBC's *The Inspection Chamber* (2017) rely on voice narration to communicate the story and use player choices as their core mechanic. Notably, *The Inspection Chamber* is controlled by voice input from the player instead of conventional controllers such as the keyboard.

It should be noted that many of the games mentioned above are not audiogames themselves; they just contain elements which can be used to construct one. These cues can also serve different functions: since audio output becomes the main vehicle for communicating information to the player, game sounds in audiogames need to fulfill a variety of roles, many of which are usually associated with game graphics. Friberg and Gärdenfors (2004), for example, divide sounds in audiogames into avatar, object, character, ornamental, and instruction sounds.

Various combinations of these types of cues and sound functions can be used to create a wide range of game dynamics, from role-playing games (Matsuo et al. 2016) to shooting games (Beksa et al. 2015) to platformers (Oren 2007) to puzzle games such as *Preludeamals* (2016).

Conclusion

While for most of their history, audiogames enjoyed little popular recognition, their recent resurgence, embodied by such titles as *Papa Sangre* and *The Inspection Chamber*, suggests

that they do yet have a potential for mainstream acceptance. This leaves hope for the reimagining of digital games as a medium that is accessible to sighted and non-sighted players alike.

Augmented and Gamified Lives

Róbert Tóth and Marianna Zichar
Faculty of Informatics, University of Debrecen, Debrecen, Hungary

Synonyms

Augmented reality; Gamification; Serious games

Definition

Gamification uses game-based mechanics, aesthetics, and game thinking to engage people, motivate action, promote learning, and solve problems (Kapp 2012). In this context, augmented reality (AR) as a popular technology can extend its functionality with the use of a camera and various sensors of a device to provide information with computer-generated methods.

Introduction

Nowadays, it is easier than ever to reach people in digital platforms, while the spread of COVID-19 is also forced the experts to find new methods to engage and support their students, clients, or participants in any field of life, but in a virtual format. This entry aims to provide a short conclusion about the key concepts and the actual trends in the field of gamification and augmented reality. After giving the definitions, examples of already existing, well-known, or innovative applications and research projects will be described to illustrate the most important takeaways about these fields. Gamification can be also applied to offline activities (Kermek 2019); however, the entry primarily focuses on a digital context.

Gamification and Serious Games

Gamification is a popular and widely used method to engage people and motivate the participants of

an in-person or digital activity. As its name suggests, the method was derived from the world of games, and it can be efficiently used in many different areas of our life, especially in the business sector and in the education. Of course, the design and the implementation depend on the actual use-case; thus, gamification has many similar, but different definitions. One of the most acceptable and abstract – thus use-case independent – definitions is Karl M. Kapp's one: *Gamification is using game-based mechanics, aesthetics, and game thinking to engage people, motivate action, promote learning, and solve problems* (Kapp 2012). Gamification can be applied to any existing process, and the elements can engage the participants with their effect. However, the original process and the functionality must be retained; gamification can only be used to extend and improve them. On the other hand, the design and implementation of a serious game can be used for the same purposes, but the method clearly differs from the definition of gamification. In the context of a serious game, a brand-new activity is being designed with the experience of a game, but with a well-defined purpose and methodology. Thus, the development of a serious game differs from the core definition of gamification (see Fig. 1).

There are many examples of successfully gamified applications or successfully developed serious games, but there are many anti-patterns, of course. The most relevant keynote is that the elements of games should be used as motivation and to provide positive feedback; thus, the goals should be precisely designed, and the activity of the user should be controlled, while negative rewards and other feedback elements should be omitted. Thus, the success massively depends on the relationships between the different elements; thus, great gamified processes and serious games implement a bunch of elements. The set of implemented elements can depend on a specified user type for which an application is being developed (Ponick and Stuckenholz 2019). As in application development, various patterns can be discovered in gamified applications and the most common elements can be easily collected and divided into groups:

Augmented and Gamified Lives, Fig. 1 A serious game which aim is to provide an environment for practicing the built-in functions of spreadsheet software products

- *Activities* – Elements that offer activities and control the user such as missions, challenges, and goals.
- *Feedback* – Elements that give positive feedback to users such as scoreboards, progress bars, charts, experimental points (XPs), and experience levels.
- *Rewards* – Completions of activities should be rewarded with badges, experimental points (XPs), lifelines, privileges, and domain-specific items.
- *Sociality and interaction* – Users have profiles and can see each other's results in scoreboards, charts. They can compete in duels or special interactive activities.
- *Time* – This element always appears in a combination with another elements and is an important factor in the control of the user.
- *Design and modality* – Both in digital and in-person contexts, all the use of other elements depends on the user experience (UX) which is based on the design and the modality.

Augmented Reality

Augmented reality (AR) applications use the camera and various sensors of a device (typically cell phones, tablets) to enhance the visual experience with computer-generated perceptual information. In the last decade, a great number of AR applications have been developed in many different areas. AR is a preferred alternative to virtual reality (VR) because no additional devices (only the built-in ones) are required. Also, the latest mobile devices are designed with several additional cameras and sensors to improve the quality of their AR functions. The first well-known applications with AR functions were games, but the AR can be used in education, tourism, military, or for social purposes. According to a widely used library, AR functions can be divided into four main groups:

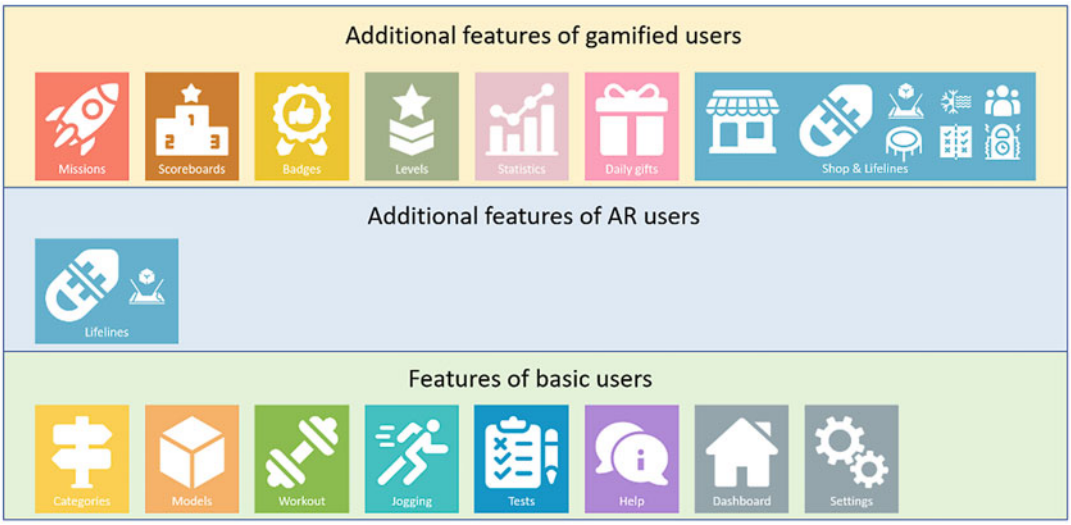
- *Instant placement* – This function scans for flat surfaces, then the users can instantiate 3D objects and place them on the detected surfaces. More interaction (such as scaling, moving the objects) can be achieved easily.
- *Cloud anchors* – This function is the extended and improved version of the instant placement in which multiple users can interact in the extended reality.
- *Augmented images* – This feature depends on a computer vision algorithm which simultaneously processes the picture of the camera and searches for features of specified images. With the use of this feature, users can instantiate 3D objects by scanning images.
- *Augmented faces* – This function is widely used in mobile operation systems, messaging applications and other gadgets. The face of the user is being detected with a computer vision algorithm and various objects can be put on them. After that, each movement of the user will be tracked by the sensors and the 3D objects will move in a synchronized way.

Concurrent Applications

It is clear that motivation is one of the most important factors in the success of a learning process. In the last decades, many platforms and educators have introduced gamification to engage their students. The most well-known language learning environment is one of the best examples for a carefully designed and precisely implemented gamified process (Huynh et al. 2018). It offers the basic mechanism of an online learning process – topics, exercises, notes, tests – but also engages its users with the friendly interface, social items, rewards, and time elements. Gamified elements can be discovered in loyalty programs of various companies, such as airlines (https://www.miles-and-more.com) and restaurants (Tyson 2019). The goal in the first approach is quite simple however, complex systems can be designed on the collected data as well. Users create their profiles, so their transactions can be associated and tracked. Users collect points, achieve milestones or levels, and get privileges or discounts, while companies can execute data mining algorithms to analyze their behavior. The well-designed loyalty programs contain the most

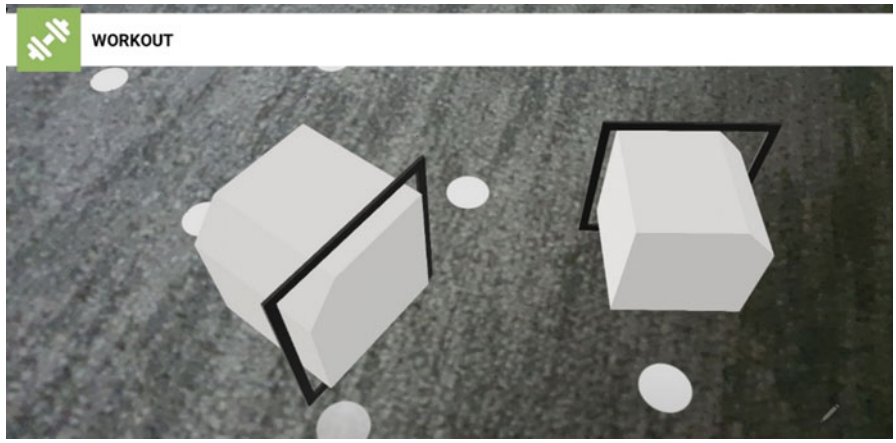
common elements of gamification. Fitness applications also use gamified elements to motivate the users in the hard process of diets. In the most popular applications, users can choose their goals, while the applications can automatically offer goals, rewards, reminders, and give feedback in the form of various statistics. However, in the last years, gamification elements are being applied to games that are distributed in various formats. Games with very simple logic and user experience implement the most common elements such as leaderboards, XPs, missions, time, and sociality to improve the user experience of the game. However, complex games and game stores also offer gamified elements to promote their products, engage and reward their users. On the other hand, well-known applications are starting to motivate their users to contribute by applying a few elements such as points, levels, and badges (see Fig. 2).

The first well-known AR application was released in 2016 in the form of a game which was based on a Japanese anime and its fictive characters (Rapp et al. 2018). The characters



Augmented and Gamified Lives, Fig. 2 Features of an application (Tóth et al. 2021) which offers Mental Cutting Test exercises to its users. Gamified elements can be implemented without changing the basic logic of the application

Augmented and Gamified Lives, Fig. 3 The visual cookbook uses an AR function to support its users who live with disabilities



Augmented and Gamified Lives, Fig. 4 The AR function of the previously mentioned learning application offers an opportunity to instantiate the model of the actual exercise and interact with it

were placed on selected geographical coordinates and users had to find and catch them with their mobile phones. Many other games are still be developed based on AR functions. People living with disabilities can be supported with AR applications designed to give some help for them in an activity that is trivial for others. Six European universities and a nongovernment organization run a project that focuses on how emerging technologies (including AR) can be used in developing such applications (Barbas et al. 2020). Figure 3 shows a visual cookbook application which is already published, where augmented image function is used to instantiate the ingredients of dishes (Pevec 2020).

Of course, AR is a perfect tool to be applied in education as well. Teaching and learning of courses where demonstrations are of high importance, can be supported by AR applications (Nørgård et al. 2018; Salinas et al. 2015; Grunewald Nichele and do Nascimento 2017). Thus, more students can access the extra information and online activities can also be supported (see Fig. 4). A well-known toy manufacturer company has also started to develop innovations with the use of augmented functions. Their applications are based on the augmented image function, offering the opportunity to instantiate the models of their current brochures (https://play.google.com/store/apps/details?id=com.lego.catalogue.global), while brand new product themes were also introduced massively built on augmented functions. Thus, children can interact with their sets gaining more experience. The largest tech-companies are also engaged in the mission to develop and distribute AR features to enhance the use of their products and provide tools for the developer community. The navigation of a well-known software (Ranieri 2020) now offers an AR function to provide useful information in an enhanced format, with the use of instant placement function. On the other hand, a new search function was also introduced with the use of which users can directly instantiate 3D models and interact with them (https://support.google.com/websearch/answer/9817187). Also, they provide a well-detailed and flexible used API for developers who want to develop their AR applications, based on the same core. Multiple platforms and devices are supported, that were produced in the last few years with the latest versions of operation systems. On the other hand, sample projects and the source codes of the development kits are published in public repositories (https://github.com/google-ar/arcore-android-sdk).

Augmented Learning Experience for School Education

Satyaki Roy, Pratiti Sarkar and Surojit Dey
Design Programme, Indian Institute of Technology, Kanpur, Uttar Pradesh, India

Synonyms

Augmented reality; Gamification; K-12 education

Definition

Augmented reality is one of the technologies that works in real time to overlay virtual computer-generated graphics on to the real-world environment so as to provide the users with open-ended experience.

Gamification involves the use of several elements of game design in a context that does not actually belong to a game. This provides a playful experience to users and keeps them engaged and encouraged to attain the defined goals.

The K-12 education is a combination of primary and secondary education in schools which starts from Kindergarten, till 12th standard.

Introduction

The years are progressing with the development in technology. Augmented reality (AR), being one such technology, has been a key research area from quite a long time and has been applied in various domains. In the field of education and learning, several works have been done to improve the understanding and knowledge using AR. Gamification has been another means by which the students are made to be engaged with the experiential learning and stay motivated. With the advancements in the Internet usage and development of portable electronic devices, these two technologies are now reachable to everyone.

These means are being introduced in various sectors including education and learning to enhance the existing experiences. In the current education system, a lot of data is supposed to be memorized for writing the examination. This requires a need to reduce the cognitive load of the students with the developing technologies to make it easy for them to memorize and at the same time enjoy the learning experience.

In this entry, a case study on geography subject has been discussed to show a gamified way of learning maps using augmented reality for K-12 education system in schools to deliver better understanding, easy memorizing, and incremental learning.

K-12 Education System in Schools

With the advent of technology, K-12 education system in numerous schools is gaining importance and various methods of imparting knowledge have been adopted to make it more engaging for the students and enjoy the learning experience. In this form of education system in schools, a lot of attention is given to individual learning so that the students can on their own explore and develop their learning and understanding skills. Teachers are introducing various interactive activities as the mode of learning for the students to provide them an easier way of better understanding about what they are studying.

In many schools, blackboards are now getting replaced by projector screens to provide digital learning experience. Numerous schools are adopting such smart-class solutions where teachers project the digital content related to textbook on the screens for the students to better understand the concepts. These digital contents include 2D or 3D animations, audios, videos, etc. Students are also able to practice and learn at home on their own using various online modules. With the introduction of more evolving technologies and digital platforms in the K-12 education system in schools, it is believed that there will be growth and development in the learning capabilities of students.

Augmented Reality in School Education

The technology of augmented reality (AR) helps in interactively combining the virtual and real world in real time. AR systems are considered to work with the combination of various factors. It overlays the virtual information layer on top of the real surroundings instantly. The contents of the computer-generated virtual overlay have to be interactive and meaningful in the real environment (Azuma et al. 2001). In the course of many years, the importance and application of AR has been realized in several domains.

AR helps to visualize the virtual objects as real. One can see the live 3D representation of the computer-generated virtual imagery data. It can thus help students to interact with the 3D spatial structures and enhance the learning skills. In the field of school education, the applications of AR was realized in some of the subject areas that included astronomy, chemistry, biology, mathematics and geometry education, and physics (Lee 2012). Through the evolution of gadgets like personal computers, smartphones, tablets, and other electronic innovations, AR has become more powerful in becoming a prominent technology.

The AR technology in school education can be observed through mediums like AR books, objects modeling, AR games, discovery-based training, and skills training (Yuen et al. 2011). AR can potentially increase the collaboration and understanding between teachers and students in classroom. While teaching in classes, many a times the teachers and students are not on the same mental platform. Teachers try to make the students visualize some concepts in 3D but are unaware if the students are able to do it or not. With the application of AR, now the 3D representation of the concepts is shown to the students in class which highly aids their understanding. Classroom learning using AR gives a very engaging experience where students can look at things from every angle and this turns to be very useful in explaining many things from textbook like the solar system, atomic structures in chemistry, etc. AR books are also an important innovation which bridges the

gap between the digital and physical world. Because books are printed media, they have some limitations like poor printing quality, dullness, etc. But the conversion of 2D contents of the textbook into 3D objects in real environment helps to enhance the learning experience. Such tools have also been developed which can convert 2D sketches into 3D objects, using which students can develop 3D models in space. A lot of applications have been developed around games in AR as it is believed that games can play a key role in keeping students motivated and can also help them in grasping the concepts easily. There are some AR applications which during the field trips to museums, historical spots, caves, etc. display the overlaid information on the real environment, making it an interactive learning experience. Thus, the means of providing the AR experience may vary with the mode of teaching.

Memorization Using Augmented Reality

In the school education system, there are multiple subjects in each standard. Further, each subject has multiple chapters which the students have to understand, learn and recall at the time of examination. Thus, the students find it a challenging task as there is a lot of data that they have to memorize.

Several researches have been done to find the relationship between AR and memorization for providing a better scope in school education. Among the recent works, the use of an AR application has been observed to display visual directives at the location of some drawers for easy memorization of the visually displayed objects (Fujimoto et al. 2012). In some cases, marker-based AR has been used to make users learn foreign language by displaying 3D objects and their corresponding spelling and pronunciation (Beder 2012). Among the various techniques to memorize, memory palace memorization method where a user makes use of the familiar spaces to construct their respective memory palace to memorize has been applied and observed using AR (Rosello et al. 2016).

The traditional method of classroom teaching in schools can be improved by providing the students with interactive visualization of 3D objects to give them the real-life interactive experience to understand better and enable easy retention of the shown content.

Gamification in Education

Gamification helps a student to stay engaged and motivated with the learning methods. It is now emerging as a useful tool in various domains including school education. Viriyapong et al. developed a game that helps in escalating the learning experience of mathematics for high school students using game methods. With the focus on plotting linear and polynomial functions on graph using coefficients, the game motivates the user by providing points for each correct answer based on the time taken to answer. The difficulty level increases at each level of the game (Viriyapong et al. 2014). Another game is being designed that uses spaced repetition with a gamified experience to enhance STEM (science, technology, engineering, and mathematics) education for students of K-12 education system (Yeh et al. 2016). Many such gamified experiences have been provided across various subjects for the students to stay motivated toward learning new concepts.

For the implementation of gaming in AR, several elements can be used such as points, levels, badges, experience points, leaderboards, challenges (Nah et al. 2014). The introduction of these elements brings up engagement, participation, motivation, enjoyment, performance, recognition, status, sense of accomplishment, and sense of achievement in any game. But it becomes difficult to make the whole game, especially an educational game interesting and motivating by using only one of these elements. Best results are obtained when these elements are used in combinations where they are interlinked with each other. These elements are to be incorporated in the game in such a way that it connects the student with the gameplay and their fellow players.

Combining Augmented Reality and Gamification in Education

Various attempts have been made for combining AR and gamification in the field of school education. AR system can be either marker-based or marker-less (Johnson et al. 2010). In marker-based AR system, the camera of the device first identifies the marker related to any image or associated data, then matches with the related content in the database, and finally superimposes the related 3D visualization and/or audio onto the real world. Marker-less AR on the other hand does not require any former information about the real world environment. It instead involves the use of GPS and compass of the AR device connected through Internet and applies image recognition methods to track certain defined features in the live environment and overlay the virtual content onto it.

Virtual laboratories in the real world are being introduced using "markers" to provide interactive hands-on learning and experimental experience for learning and education (Eleftheria et al. 2013). In this, a science AR book was created along with gamification. The knowledge and learning was tested through several challenges as part of game.

In another AR game, the use of GPS, compass, and Internet in a hand-held device, enables students to discover why the aliens entered the earth (Dunleavy et al. 2009). In the AR environment created, the students interact with the computer-generated characters, digital objects and solve related puzzles based on math, science, and language arts.

Thus, the feature of memorization using augmented reality and motivation using gamification can be combined to further enhance the learning capabilities of students and make it an enjoyable experience for them.

Case Study: Applying AR and Gamification in Geography

In the existing K-12 education system in schools, there is a lot of data that needs to be memorized by students to perform well in their examinations. The system focuses on dividing the whole content in appropriate modules with required amount of data and takes few examinations based on that. However, this kind of school education lacks enough motivation for the students to stay engaged with the subjects. In many subjects that are related to real life, students find it difficult to correlate because the pictorial contents they have in their books are in two dimensions whereas in real environment they are in three dimensions. Among the various subjects that the students have to learn, geography is one such course that involves a lot of information to understand as well as memorize for writing examinations. In this subject, it becomes difficult to visualize things in three dimensions, and it turns out to be even more difficult for the teachers to teach and make the students understand. In every standard, starting from class 5, the students are made familiar with different type of maps, the way to read them and the way to find latitude and longitude of a location in the map using atlas or vice-versa. Since, there is a lot of textbook data and numerous locations that the students have to keep in mind, this results in students losing the interest in that subject and studying it just for the sake of examinations. Thus, the design of an AR-based game for learning the maps easily and with interest has been further discussed.

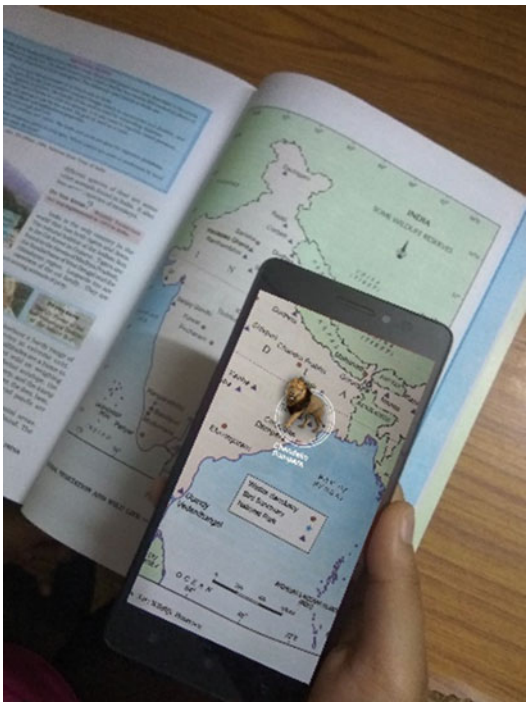
The two methods, marker-based and marker-less AR are being extensively used and explored in various works on school education. However, in this case study the use of marker-based approach has been emphasized upon for the existing geography textbooks.

In the design, augmented reality has been used to make the contents more interactive. Additional printed AR markers are provided corresponding to each map in the textbook. On scanning the markers with the AR device, users can see the maps in 3D. In the maps which show terrains, wind movements, etc., users are able to see those visual contents in three dimension. This application is based on two modules. First is to help the users memorize the locations as well as understand the related concepts and the second one is

to help them practice to mark the locations on the map.

In order to memorize the locations on the map, a 3D visualization of the map is augmented. If it is the map of wildlife reserves, for example, when the AR device is brought on the 2D map, the 3D visualization of the corresponding wildlife reserve on the map gets projected. This is followed by popping of names and related brief information in a sequential manner. The users have the option to revise the locations as many times as needed. Once the names of the wildlife reserves with their locations are memorized, one can proceed to play and score (Figs. 1, 2, and 3).

In the game, within 20 s, one has to mark a list of 12 locations. The user has the option to choose the type of map to practice with the help of the marker. The maximum number of locations marked within the time limit provides better scores. The property of spaced repetition has been used in this game for easy retention of the content. The short time limit challenge in the game helps in getting motivated to challenge their own retention capability. The user can get to see their performance on the progress meter for every time they play which ultimately help to develop confidence (Fig. 3).



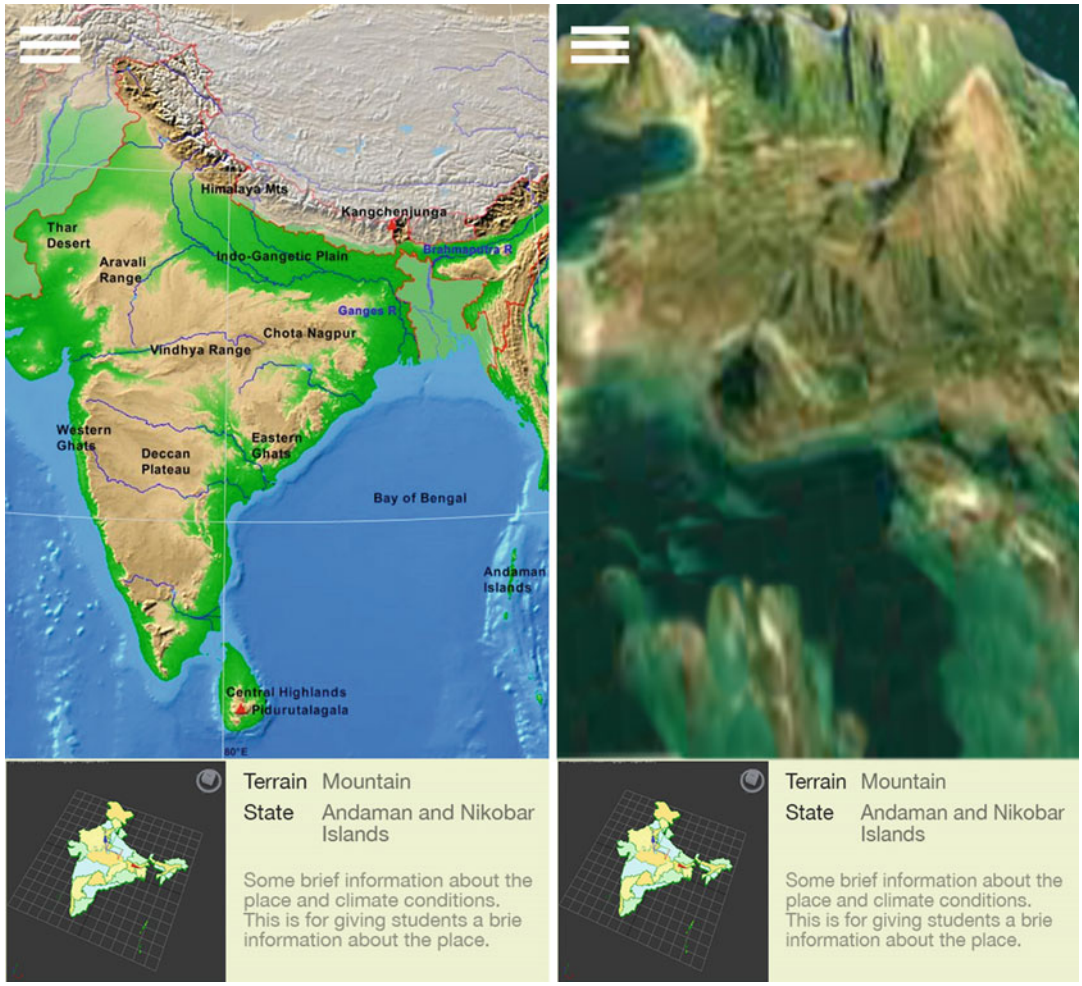
Augmented Learning Experience for School Education, Fig. 1 Demonstration of prototype

The progress meter of every player is reflected on their profile. When they feel they are confident in a topic they can raise challenges with their friends. The application persuades the user to take up challenges with the friends of their class or locality as on winning a challenge the user earns twice the number of points as compared to normal practice mode. This encourages the user to take more number of challenges.

The game consists of scores, levels, and badges for the users to stay motivated in learning the maps quickly on their own with enjoyment. For every 1000 points a level is attained and the user gets a badge for that which shows their proficiency. The user also gets badges for certain defined tasks. For example, on scoring 100 points on 3 different maps the user gets a new badge. Similarly, the user can get 25 different badges on performing such defined tasks.

Limitations of Augmented Reality

AR has significantly helped to improve the learning experience in classrooms but some issues of using AR have also been observed, most of which are the hardware and software problems (Dunleavy et al. 2009). Cases have been seen where students find it challenging to learn the new technology and respond to the corresponding activities in timely manner, thus developing some cognitive stress. In the classroom experience, at times it becomes difficult for teachers to manage the student groups involved in doing AR activities. The students also tend to lose track of their surroundings while performing the AR-based activities as they get totally involved in that. On the development end, at times it becomes difficult to create and deploy highly rendered 3D objects. This thus leads to making low-poly objects instead, which might provide less clarity in visualization. However, these challenges may be

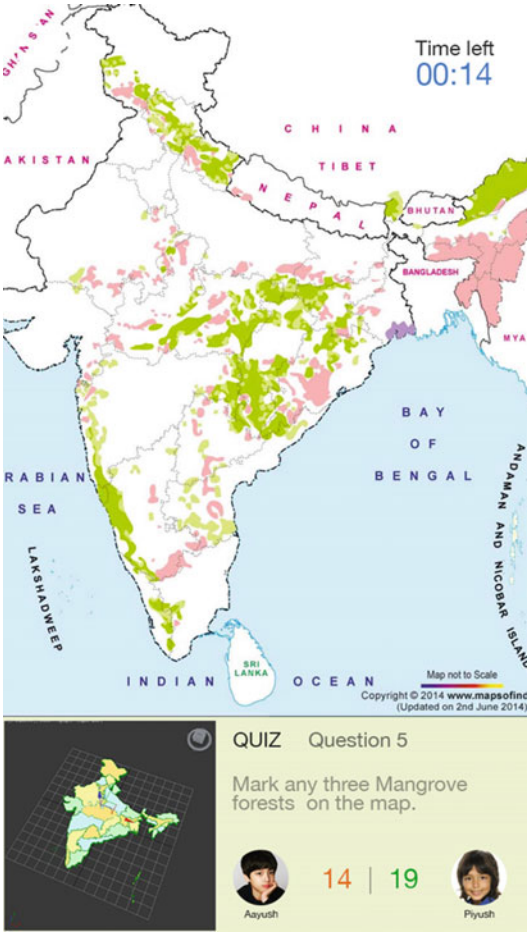


Augmented Learning Experience for School Education, Fig. 2 3D visualization of topographical map in AR

worked upon with the passage of time to provide a better AR experience.

Conclusion

This entry discussed the scope of augmented reality in school education to enhance the learning experience of students. Several researches are being done to improvise the traditional form of textbook-based teaching so as to reduce rote learning effort made by the students. Augmented reality instead provides an engaging interactive experience to share knowledge through visualization in the real world. There are various means like AR books, AR games, object modeling, and many more, by which this augmented reality–based teaching and learning is done in school education. To keep the students motivated with their learning skills, AR-based games are also introduced. These games have combination of game elements like points, levels, badges, leaderboard, etc. to encourage their participation in the game-based learning (Deterding et al. 2011). AR and gamification together makes it interactive and motivating for the students to learn easily and can help to reduce the memorizing efforts being put by the students. In the entry, one such case study on



Augmented Learning Experience for School Education, Fig. 3 Opponents competing in a stipulated time limit

learning the maps in geography using AR-based quiz game is discussed. However, there are certain limitations while using AR in school education. These include software and hardware limitations, deployment issues with highly rendered 3D objects, skills of the teachers and students to adapt to the new technology, managing the student groups, intensive involvement and avoiding the current surrounding happenings, etc. These challenges may be overcome with the evolution of the technology reachability over time. Thus, the learning can be made to be a more enjoyable experience with augmented reality getting introduced in the school education.

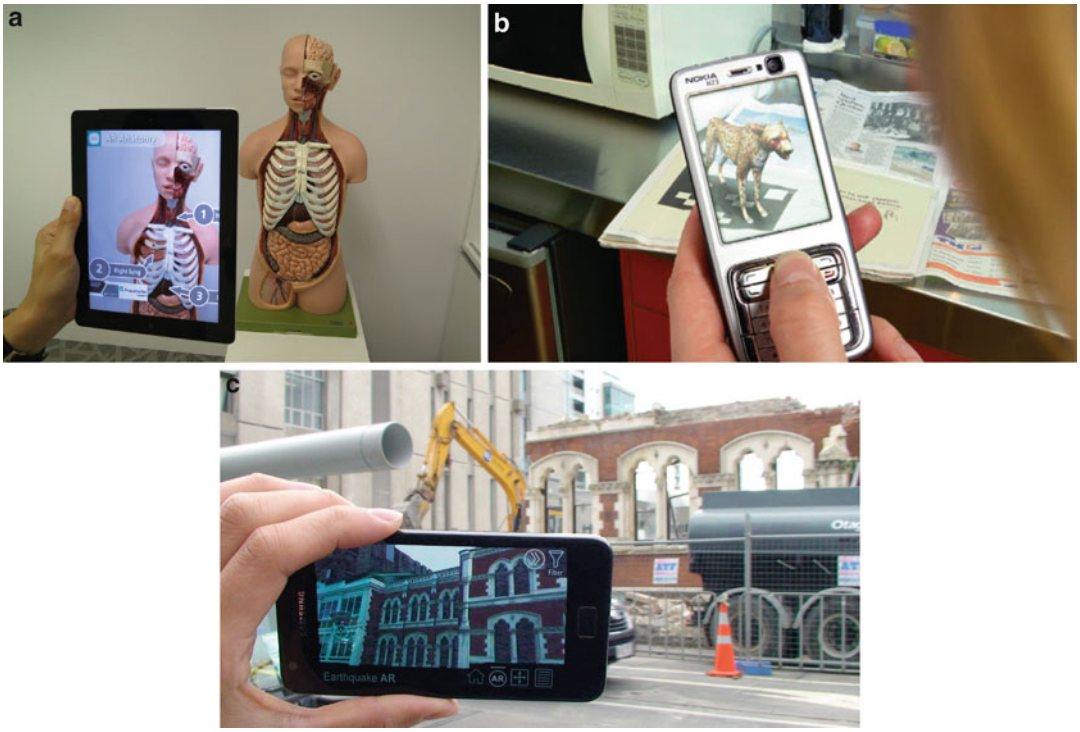
Definition

Augmented reality (AR) is technology that seamlessly adds virtual imagery over a view of the real world, so that it can be seen and interacted with in real time. Azuma says that an AR system is one that has three key defining characteristics (Sutherland 1968): (1) It combines real and virtual content, (2) It is interactive in real time, and (3) It is registered in 3D.

Introduction

AR can be used in many possible application domains, such as in medicine to show virtual anatomical structures in a real patient's body



Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 1 Examples of AR experiences (**a**) medical, (**b**) marketing, and (**c**) architectural

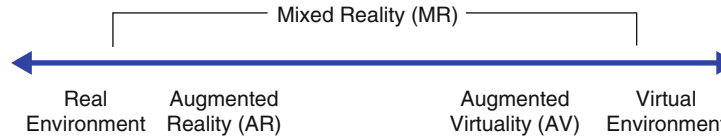
(Fig. 1a), marketing where computer graphics appear to pop out of a magazine (Fig. 1b), and architecture where unbuilt virtual buildings can appear in the real world (Fig. 1c).

In this chapter, an overview of using AR for gaming and entertainment is provided, one of the most popular application areas. There are many possible AR entertainment applications. For example, the Pokémon Go mobile phone game has an AR element that allows people to see virtual Pokémon to appear in the live camera view, seemingly inhabiting the real world. In this case, Pokémon Go satisfies Azuma's three AR criteria: the virtual Pokémon appears in the real world, the user can interact with them, and they appear fixed in space.

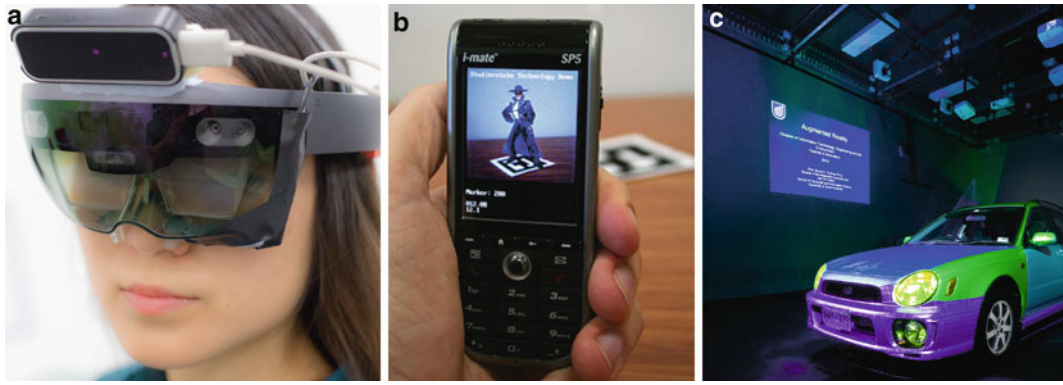
AR is complimentary to virtual reality (VR), technology that tries to fully immerse a person in a computer-generated environment. While AR uses virtual information to enhance a user's interaction in the real world, VR separates people from the real world entirely. AR and VR can both be placed on Milgram's virtuality continuum (Milgram and Kishino 1994) that arranges computer interfaces according to how much of the user experience is replaced by computer graphics (Fig. 2). At the left end of this continuum is the real world with no virtual information, while VR is at the right end, where the user's entire experience is computer generated. Mixed reality is everything in between, including the overlay of virtual content in the real world (AR) and adding elements of the real world into VR (virtual reality).

Augmented Reality Technology

Azuma's definition of AR provides guidance as to the technology required for AR entertainment systems. To combine real and virtual content, there needs to be some display technology where both can be seen at the same time. To allow the user to interact with the virtual content, there needs to input technology. Finally, to create the



Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 2 Milgram's virtuality continuum and mixed reality technologies



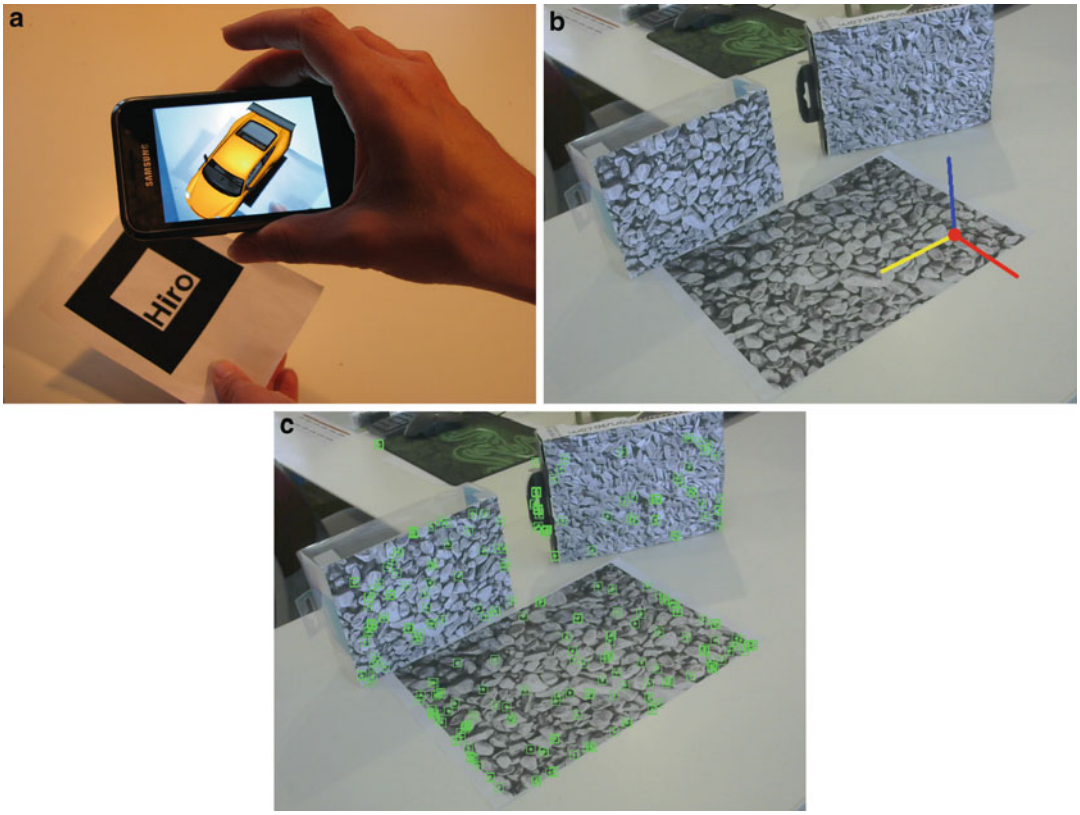
Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 3 (**a**) Head-mounted AR, (**b**) Handheld AR, (**c**) Spatial AR

illusion that the virtual content is fixed in space tracking technology needs to be used to track the user's viewpoint.

There are a wide variety of AR displays, which can be categorized into three types depending where the display is placed: head-attached, hand-held, and spatial (Davis et al. 2007) (Fig. 3). Head-attached displays include head-mounted displays (HMD), head-mounted projectors, and retinal projection systems which shine images directly into the eyes. AR HMDs can be optical see-through (OST) which use transparent optics to enable the user to see virtual images directly overlaid on the real world, or video see-through (VST) which displays computer graphics overlaid on a video of the real world. Hand-held AR displays are the most common and include devices such as mobile phones, tablets, and small projectors. Finally, spatial displays are those that include using a fixed projector to shine virtual content onto a real object, such as a car, and are often used as public displays for multiple people.

In terms of interactivity, there are a wide variety of different input devices that can be used, often depending on the type of AR display. For example, for hand-held AR the display screen is usually touch-enabled and so many hand-held AR systems use touch input. Some HMD-based AR systems have additional sensors that track the users' hands and so enable gesture interaction. In this case, it can be very natural for users to reach out and grab the virtual content that appears in space directly in front of them. Finally, for spatial AR the experience is often at a larger scale and so cameras can track a user's full body motion to enable them to interact with the AR content.

The final requirement for an AR system is to have some form of user viewpoint tracking so that the AR content can appear fixed in space while the user moves around. There are many different tracking approaches that can be used; however, for indoor-based systems, computer vision methods are the most popular. Marker-based computer vision tracking enables a user to point a hand-held or head-worn camera at a known printed image, have the camera pose calculated relative to the image, and then draw graphics overlaid on the marker (Fig. 4a). More recently, software has been developed that supports simultaneous localization and mapping (SLAM) and can calculate the camera's position without knowing anything about the users' environment (Fig. 4b). Outdoors, it is common to use GPS-



Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 4 (**a**) Marker tracking, (**b**) SLAM Tracking Points (Courtesy of Huidong Bai), (**c**) SLAM Axis Overlay (Courtesy of Huidong Bai)

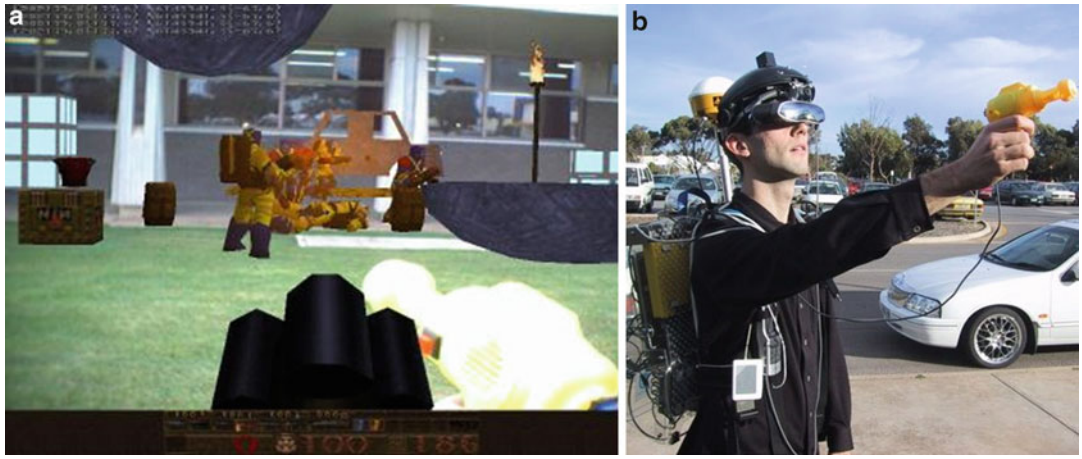
based systems combined with computer vision or inertial compass input to find the user's location. Most mobile phones have cameras, GPS, and inertial sensors in them and so have all the technology needed for AR tracking.

History of Augmented Reality Gaming

The history of AR gaming applications began nearly fifty years ago. In 1968, Ivan Sutherland created the first complete AR system with a very bulky see-through head-mounted display (HMD) connected to a mechanical head tracker, showing very simple graphics (Sutherland 1968). Following on from this the US military experimented with HMDs and heads up displays (HUDs) that were designed to overlay vehicle instrument information over the real world, for example providing a pilot with an AR view of instruments while flying.

In the late 1980s, several universities began conducting research in the AR space, developing various fundamental technologies. For example, at the University of North Carolina researchers created novel AR displays and tracking technology. The University of Toronto had scientists exploring input devices and the human factors of AR, while people at the University of Washington and Columbia University explored collaborative and mobile AR systems, among other topics.

By the mid-1990s, enough basic research had been completed that people could begin to explore the application space. The first complete mobile AR systems were developed using backpack computers, and people began to explore how AR could be applied in medicine, education, engineering, and other areas. For example, engineers



Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 5 (**a**) ARQuake. Player view, (**b**) ARQuake. Backpack system

at Boeing were using AR to help with creating the wire bundles for aircraft. Boeing engineer Tom Caudell published the first research paper with the term "augmented reality" in it (Caudell and Mizell 1992), and this led to many other companies developing industrial applications.

By the early 2000s, the underlying technology was reaching maturity, and so the first widespread entertainment applications of AR began to appear. In 2002, ARQuake (Thomas et al. 2002) was an early port of a popular commercial game to a backpack AR system. The Quake game was modified to use a real university campus as the setting for an invasion of monster's players run around the real campus seeing virtual monsters moving around in the campus setting (Fig. 5). This became a forerunner of many mobile AR games that were released a decade later on mobile phones.

Around the same time, there were several examples of indoor AR gaming experiences developed. This includes the indoor mobile AR game, MIND-WARPING (Starner et al. 2000). This employed an HMD and allowed users to physically walk/run throughout a floor of a building fighting with virtual monsters that were controlled by a second remote player on an interactive table top display. The mobile nature of the equipment allowed for AR information to be attached to physical locations in the space, to tracked physical objects, and to the game players. This created a new type of location-based gaming experiences.

The employment of a table top as an AR gaming surface provides for several interesting user interface opportunities for HMD, hand-held or table top-projected AR entertainment applications. The games may range from extensions to traditional non-computer-based games, such as AR Chinese checkers (Cooper et al. 2004) to new robotic interaction games such as Augmented coliseum (Kojima et al. 2006). There are many advantages to playing games on a computer rather than on a physical board, such as the ability to introduce animation and other multimedia presentations. The animation can do more than add excitement to the gameplay, it can also help the players learn the game and understand invalid moves.

In 2006, Fox Sports began to implement AR into their sports broadcasts. Initially, limited to NFL football, it later moved to other sporting codes. AR was used to show the player stats and scores as a virtual billboard that occupied an unused section of the field. More recently, BT Sports in Europe has introduced AR technology for describing soccer plays (Fig. 6), and AR enhancements were shown in the most recent Olympics.

In 2007, Sony released the Eye of Judgement game. This used a camera with the PlayStation

Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 6 AR soccer strategy (BT Sport)

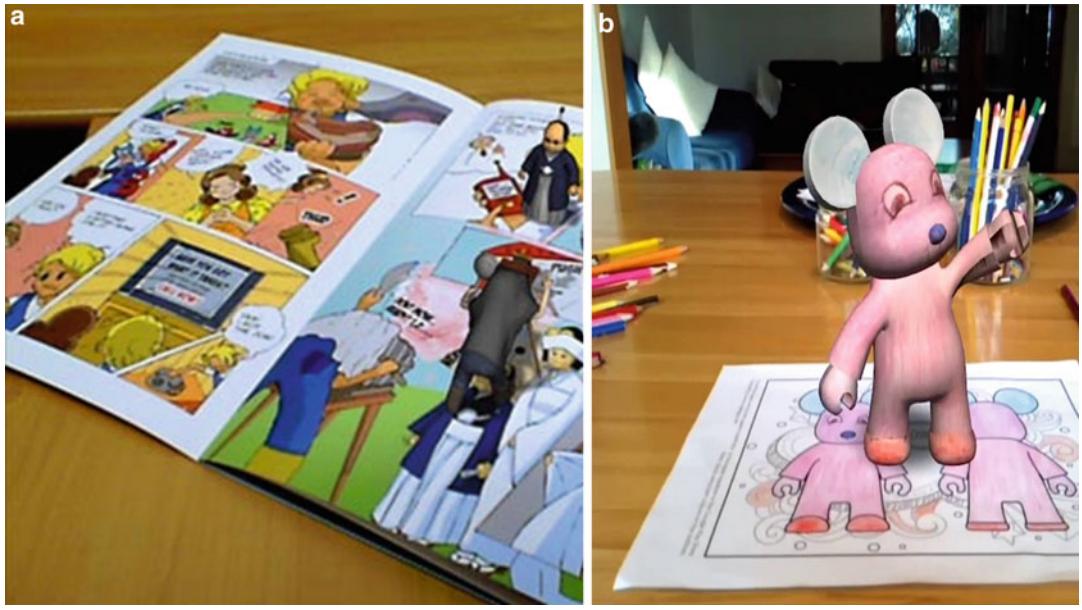
console to show virtual monsters on real cards. It was a face to face multiplayer game where players looked at a TV screen to see the AR view. The game used the camera to show a live view of the cards overlaid with virtual game characters. As players put the cards next to each other, the animated characters would battle each other. It sold over 300,000 copies, making it the most successful AR entertainment experience at the time.

Around the same time processing and graphics power on mobile phones had grown to the point where they could run mobile AR applications. The first AR computer vision application for a mobile phone appeared in 2004 (Mohring et al. 2004), followed soon after by AR Tennis, the first collaborative AR game on a mobile phone (Henrysson et al. 2005). In AR, Tennis players sat across from each other playing an AR tennis game using their phones as real rackets, viewing virtual content attached to a real marker between them. By 2007, phones had integrated GPS and compass sensors in them enabling the first mobile phone outdoor AR experiences, such as viewing virtual buildings in the real world. This opened AR to the masses and allowed developers to build a whole new class of entertainment applications.

Current Augmented Reality Entertainment Applications

Following from the early beginnings reviewed in the previous section, there are a wide range of current AR entertainment applications that show how AR can be used in many different entertainment domains. Initially, AR mobile apps were simple and used for information browsing applications such as a bank app that places virtual tags in the real world showing were ATM machines are. Recently, these AR apps have branched into location-based gaming with the most well-known being Pokémon Go (2017) (and its predecessor Ingress). These games allow players to travel to a location and do battle with virtual enemies which are overlayed on the real world. Being the fastest mobile app ever to achieve more than $1 Billion USD in revenue, Pokémon Go shows the huge potential that combining location-based gaming, AR and a well-known brand can have.

Another popular category for mobile AR is interactive books and coloring experiences. Beginning with the MagicBook (Billinghurst et al. 2001), there are many AR book experiences. Typically, these allow users to view a normal book through their mobile phone and see the pages come to life with interactive AR content (Fig. 7). These are particularly popular for children's stories or educational books. A variation of this is the AR coloring application which allows children to color pages and then see AR content appear out of the page with their colors on the content. This was popularized by the company Quiver (Website 2017), but has since been developed by dozens of other companies around the world. Children really enjoy being able to see



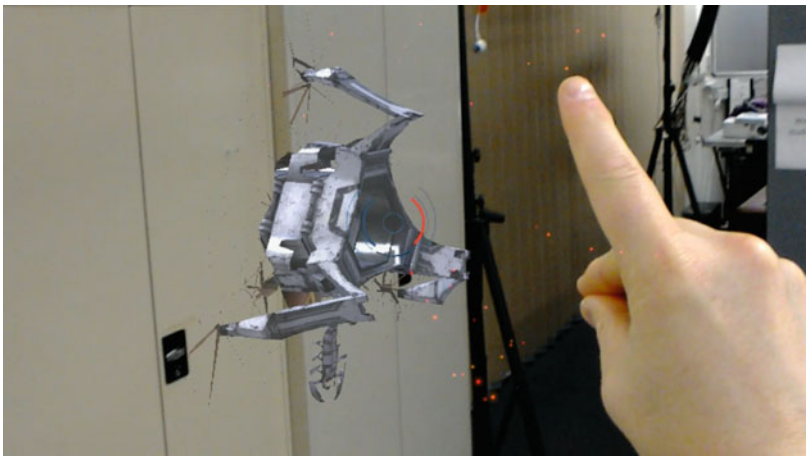
Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 7 (**a**) AR book, (**b**) Quiver AR coloring book

Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 8 Microsoft RoomAlive (Courtesy Microsoft Research)

virtual characters that they have colored come to life.

Spatial AR technology has been used to create room scale AR entertainment applications. For example, Microsoft's Room Alive spatial AR system turns living rooms into interactive AR play spaces (Jones et al. 2014). Depth-based cameras are employed to map the real environment and to capture gestures and movements of people in the space. In this way, graphics can be seamlessly projected on the walls and the user can move freely around the space and interact with the virtual content (Fig. 8). For example, a hand-held gun prop can be used to shoot the virtual creatures in the living room.

There are few widely available AR HMDs, but the Microsoft HoloLens (Website 2017) shows the type of AR HMD-based entertainment



Augmented Reality Entertainment: Taking Gaming Out of the Box, Fig. 9 Augmented reality gaming. Microsoft HoloLens RoboRaid

experiences that are currently possible. The HoloLens contains depth sensors that can map the user's surroundings, allowing an application to make use of the surrounding environment and annotate 3D objects over that environment. A good example of this is RoboRaid (Fig. 9:) where the user's room is attacked by aliens that break through the real walls and try to defeat the user. This is achieved by the HoloLens creating a 3D map of the room and interpreting where the physical walls are in the room them allowing the game to apply game oriented textures to the walls.

Conclusion

As can be seen from the previous sections, AR has a long history and entertainment is one of the widespread uses today. AR is pervading industry with new start-ups appearing almost weekly, while older established corporations, such as Apple, have been buying up these start-ups almost as fast as they appear. It's clear that they see a future in the technology.

One of the reasons for this growing popularity of AR is that it offers a fundamentally different entertainment experience. Non-AR experiences typically focus the user on a screen (mobile games) or completely immerses them into a digital space (VR). On the other hand, AR expands the users' interaction with the real world, whether encouraging people to walk outside to find Pokémon's, or motivating children to read more by turning their books into an AR play space.

Another area of endeavor is allowing users to grasp and feel the texture of virtual objects in AR. Devices such as Massie's Phantom (Massie and Salisbury 1994) provide a mechanical arm held by a user's fingers allowing computer-controlled haptic feedback to be programmed. Simon et al. (2014) have been investigating the use of a technology called layer jamming to provide haptic sensations with the low-profile actuator that is encapsulated in a mitten. This technology has both benefits in that it is low profile but disadvantages as it requires a vacuum source to activate the actuators providing the stimulus.

Spatial augmented reality (SAR) (Fig. 3c) has a lot of potential for gaming and entertainment as it is not a solitary experience. Because the projections are independent of the user, many users can participate in a shared experience; most other AR approaches do not directly support shared gameplay due to the nature of the projection, e.g., helmet or phone. SAR games could include shared gaming environment (AKA Star Treks' Holodeck) where people share the experience. However, due to the added a complexity, cost and calibration challenges it has not been adopted at the same rate as other forms of augmented reality. Cooperative and competitive games will become very playable once the problems of cost and calibration are solved satisfactorily.

Overall, AR provides unique entertainment options not available with other types of

digital media. However, in many ways developers are still just beginning to explore the full potential of AR for entertainment. With new devices and research outputs becoming available, future AR systems will be a significant advance over those available now. There is a bright future ahead for AR entertainment experiences.

Definitions

Augmented reality for human-robot interaction in industry is the usage of augmented reality technologies for displaying computer-generated digital contents, correctly aligned to real objects, in order to enhance and enrich the communication interface of users, which operates robots in an industrial environment.

Introduction

The industry domain has taken advantage of augmented reality (AR) since its origin (Sutherland 1968): technicians are often

involved in complex assembly, repair, or maintenance procedures, and they need to refer to instruction manuals to complete their tasks (Caudell and Mizell 1992). However, these activities often require a high cognitive load due to a continuous switch of the attention between the physical device and the paper manual (Henderson and Feiner 2007). AR can efficiently overcome this issue providing the same content in a digital form and properly displayed on the physical object involved in the task.

In this entry, AR technologies adopted to visualize digital contents in industry, the different kinds of robots involved in, and the most common tasks which benefit of AR contents are discussed.

Technologies

Among human sensory inputs, sight, hearing, and touch are currently the senses enhanced by an AR system through digital contents. However, since industrial environments may provide different kinds of limitations depending on the task, such as anti-noise headphones or gloves, the AR content is usually provided visually. Different devices can be adopted to display the AR content depending on the task and the environment. Overall, an AR system is characterized by three blocks: a tracking system, a content generator, and a combiner.

Tracking System

The tracking system has the task to establish an absolute reference system, based on some features related to the environment: this reference system is fundamental to properly display the augmented reality content with respect to the user's view and the real-world objects. The tracking system is called object dependent if the reference system depends on the position of a real object: this kind of systems adopts computer graphics algorithms to identify the object from frames of the environment provided by a digital camera. Other, less common solutions consist of inertial, mechanical, and magnetic tracking systems or involve the usage of absolute references such as GPS coordinates (Foxlin 2002).

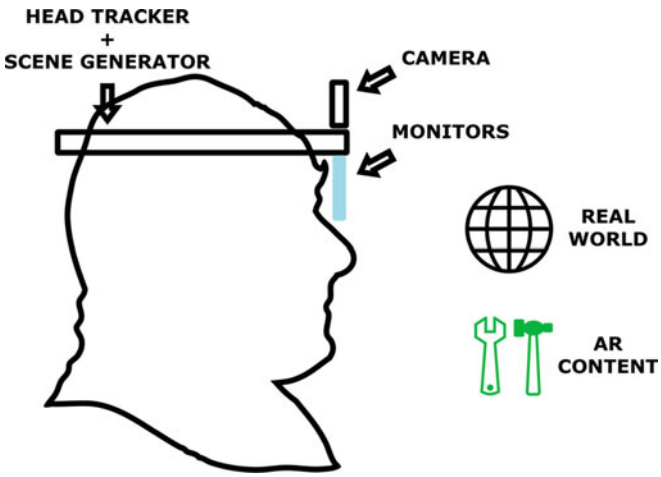
Content Generator

The content generator has the task to compute the graphical content to be displayed depending on the coordinates provided by the tracking system and the frames provided by the digital camera.

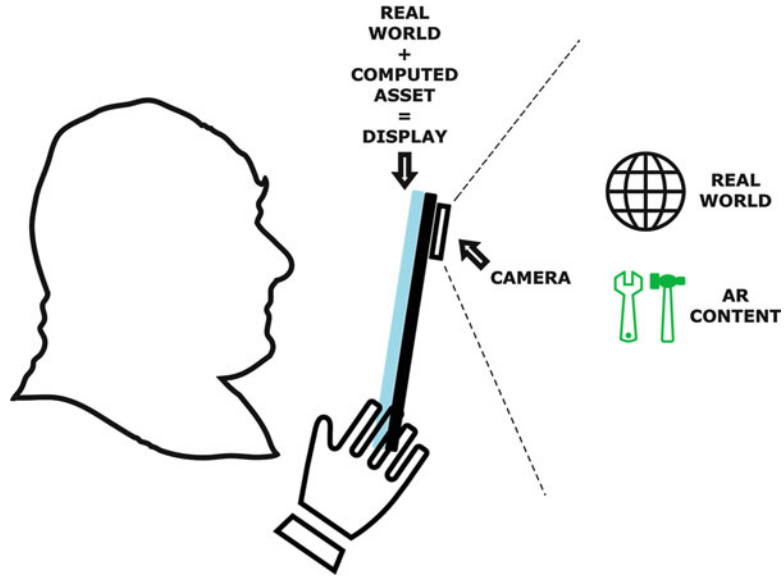
Combiner

The combiner has the task to overlap the assets to the user view. It acts in different ways according to the used AR paradigm.

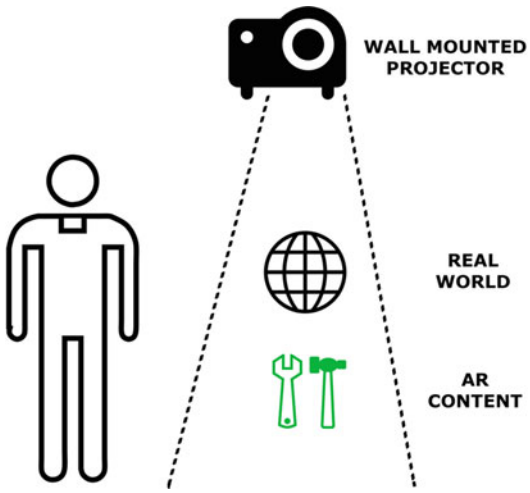
Optical see-through devices blend physical and virtual objects holographically using transparent mirrors and lenses (Fig. 1). These devices are wearable and most of the time also mobile.



Augmented Reality for Human-Robot Interaction in Industry, Fig. 1 Optical see-through AR system



Augmented Reality for Human-Robot Interaction in Industry, Fig. 2 Handheld AR system



Augmented Reality for Human-Robot Interaction in Industry, Fig. 3 Projective AR system

Moreover, since it is possible to wear them like glasses, the user's hands are free, which is usually mandatory in industrial tasks. One disadvantage of this kind of devices is the limited field of view that may cause clipping of virtual images at the edges of the mirrors or lenses. Moreover, it is difficult to occlude a real object because their light is always combined with the virtual image due to the lenses properties. Finally, other devices (e.g., physical trackpad, joypad, or keyboard) are required to be added to the system to provide a proper interaction interface.

Handheld technologies include all the devices that allow to display both the physical world, recorded through a camera, and the AR content on a display (Fig. 2). These devices are usually mobile, e.g., smartphones and tablets, since the user needs to freely move them in order to frame the point of interest in the environment and experience the AR content. The most common disadvantages of handheld devices are two: firstly, the need to use one or both hands to handle the devices, thus making them unavailable to perform tasks; secondly, the user may experience disorientation for parallax effect due to the camera position with respect to the viewer's true eye location.

Projective devices allow to directly display AR contents over physical objects (Fig. 3). They do not require special eyewear and accommodate the user's eyes during focusing. Moreover, they can cover large surfaces for a wide field of view. In the industrial domain, these devices are usually adopted to display AR content on a big industrial robot, such as robotic arms. Commonly, projection surfaces may vary from flat, plain colored walls to complex scale models. The main limitation of this technology is that the AR content is perceived as bidimensional instead of three-

dimensional. Other common disadvantages comprehend occlusion and the need for other input devices for interaction. Moreover, projectors need to be calibrated each time the environment or the distance to the projection surface changes.

Robots

AR technologies are usually applied to human-robot interaction (HRI) with two categories of industrial robots: robotic arm manipulators and automated guided vehicles (AGVs).

A robotic arm manipulator is defined as an n-degree-of-freedom (nDoF) arm robot. It is composed of links connected by joints that are controlled by using either DC or brushless electric motors. Their positions are sampled by means of encoders, and the joints' velocities are measured with tachometers. Joints are divided into two different categories: revolute and prismatic. Revolute joints allow rotations along one local axis (usually the z-axis), whereas prismatic joints allow translations along one local axis (usually the z-axis). Robotic arms are also equipped by different custom tools depending on the task to accomplish: these tools are positioned at the end of the kinematic chain and are called end-effectors.

AGVs are vehicles that can move along predefined path and predetermined directions automatically and autonomously, without human interference. They are usually equipped by sensors that allow them to identify and eventually avoid obstacles along their path. Their primary task is to transport equipment around a manufacturing facility. AGVs are equipped with automatic guiding, either electromagnetic or optical, they can follow a predefined path through visual analysis of a familiar environment, or they can use vision system to understand their location in an unknown environment.

Tasks

Depending on the type of robot considered and its task, various types of AR systems are adopted, and different AR contents are provided to the user. When used with robotic arm manipulators, technicians can benefit from AR systems to visualize one or more of the following features: end-effector path, end-effector direction, object (s) manipulated or involved in the task, workspace involved in the robot task, forces applied by the end-effector, and faults that occur on the industrial manipulator. When used with AGVs, the features visualized through AR usually consist of the path and workspace of the robot. In the following, each feature will be introduced and explained.

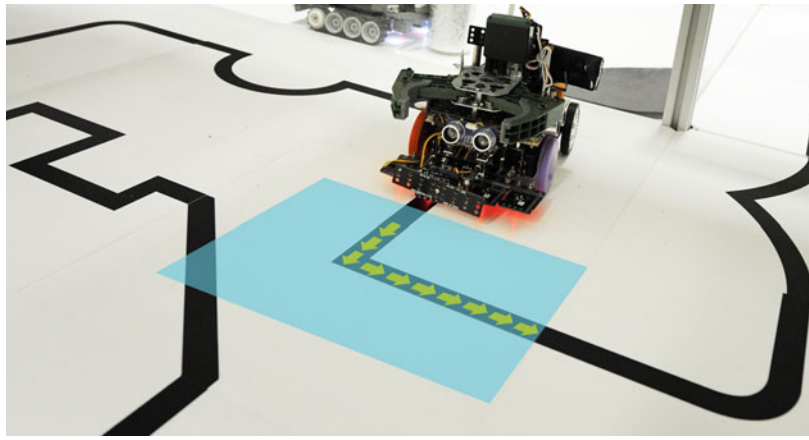
Path

Depending on the types of paths and trajectories, different AR systems can be adopted. Trajectories can be divided in 2D paths and 3D paths. The first ones are usually visualized on 2D areas using projectors mounted directly on the industrial manipulator or on appropriate supports placed nearby the robotic arm. They normally consist of one or more connected lines of the same color. The 3D paths are visualized in the real environment by means of wearable or handheld devices. It is possible to interact with both types of path using some specific tracked devices to modify them: this allows users to change the trajectories of the industrial manipulator through the interaction with the augmented reality paths.

When displaying the path of an AGV, since these robots freely move around all the environment, the AR projection system is commonly placed directly on the mobile robots. Thus, workers can work without wearing ad hoc AR devices. AGVs are equipped with projectors that allow to visualize the AGV's intentions directly on the floor of the facilities. Projectors are mounted on the AGVs at different heights; therefore the projected area varies. Data projected can represent the future path that the AGVs are going to follow by means of arrows (Fig. 4) and lines or only the occupied space (Matsumaru 2006, Coovert et al. 2014, Chadalavada et al. 2015).

Direction

Direction features are useful to understand in real time the direction of the end-effector. These features are commonly represented by 3D virtual



Augmented Reality for Human-Robot Interaction in Industry, Fig. 4 Example of AR contents used to display the AGV's path (yellow arrows) and the area that it will occupy (in blue). (Reproduced from RoboCup 2013 (CC BY 2.0))

arrows placed in the position of the end-effector (Fig. 5), and they are visualized in the real environment using wearable or handheld devices (Michalos et al. 2016).

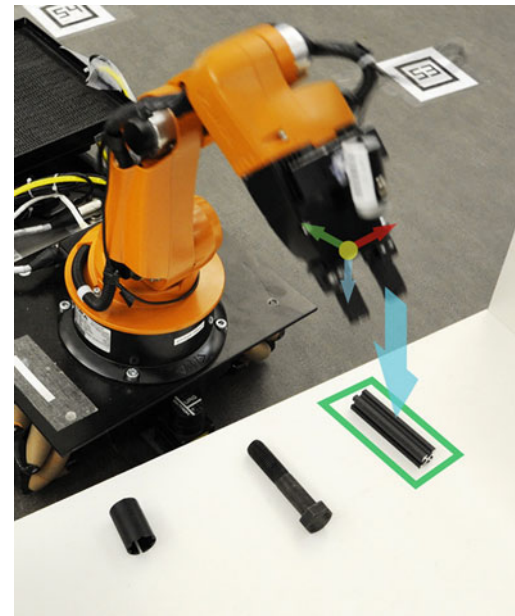
Object Manipulated

Objects that are going to be manipulated by the robotic arms can be highlighted using both 2D and 3D features. The 2D features are commonly represented by means of icons or geometric planar shapes projected directly on the object (Fig. 5). The projectors are mounted directly on the industrial manipulator or on appropriate supports placed near the robotic arm. The 3D features are commonly represented by 3D virtual replicas of the real objects that are superimposed on the object manipulated by the robotic arm (Akan and Çürüklü 2010).

Workspace

It is possible to identify two different workspaces: the first one is the workspace of a robot arm manipulator, defined as the set that comprehend all the positions it can reach; the second one is the "collaborative workspace," defined as the working area in which both the human operator and the industrial manipulator work together.

The robot workspace is commonly visualized using handheld or wearable devices. The operating area of the industrial manipulator can be represented using a 3D sphere, centered in the base of the industrial manipulator. The diameter of the sphere can also vary, depending on the movements of the end-effector.



Augmented Reality for Human-Robot Interaction in Industry, Fig. 5 Example of AR contents used to display the object to be manipulated (in green), the direction of the end-effector (in blue), and the forces on it (three axes on the end-effector). (Reproduced from RoboCup 2013 (CC BY 2.0))

The second workspace can be visualized using optical see-trough (Makris et al. 2017) or

projected AR systems (Vogel et al. 2011). Projectors are placed near the robotic arm, in an elevated position, and the "collaborative workspace" is projected directly on the floor. Optical see-trough systems are usually composed by cameras, placed in the corners of the environment. Depending on the distance of the user from the robot, at least two different areas are projected: the furthest area that is considered the safest operating area for the human worker, and it is commonly colored green and the closest area that is considered the most dangerous operating area for the human worker, and it is commonly colored red. When the human worker operates in the furthest area, the robotic arm works normally. On the other hand, when the human worker is in the closest area, the robotic arm stops or slows down its motion in order to avoid any possible damage (Fig. 6).

Augmented Reality for Human-Robot Interaction in Industry, Fig. 6 Example of AR contents used to display workspace of the robotic arm, with different colors depending on the safety for the user based on distance and arrows displaying the direction of the movement (in green) and an error state for one joint (in red). (Reproduced from Humanrobo 2009 (CC BY-SA 3.0))

Forces

Forces applied by the end-effector can be monitored and visualized using wearable or handheld devices. Forces can be represented using 3D virtual vectors, applied on the tool center (Fig. 4). The force components in X, Y, and Z are displayed as well as the resulting vector. Furthermore, the components are colored with different colors, depending on the intensity of the force (Mateo et al. 2014).

Faults

When a fault occurs on an industrial manipulator that is working side by side with a human operator, stress and anxiety may increase in the worker because he is not able to realize in real time which is the cause of the error. Moreover, since it is not possible to realize the cause of the fault immediately, the time and resources required to solve it strongly increase.

There are at least four different categories of faults that can be visualized using AR technologies: faults on the velocity sensor, faults on the actuation system, faults due to overloading problems, and faults caused by collision (De Pace et al. 2018). These typologies of errors can be visualized using both hand-handled and wearable devices. Each fault is represented using a specific 3D asset, superimposed on the error's location. Faults on the velocity sensors are represented using 3D circular arrows placed near the robotic arm's joints. These arrows rotate as long as the velocity sensor is acquiring correct data from the motor encoder (Fig. 6, green arrow). When a fault occurs on the velocity sensor, the arrows stop moving, and they change their color to red to highlight the problem (Fig. 6, red arrow). Faults on the actuation system can affect the joint's motor. If an error occurs on it, a 3D model representing the motor is superimposed on the real motor. Moreover, it starts blinking to emphasize the location of the fault. Faults due to collision can be represented using a 3D sphere center at the base of the industrial manipulator. A collaborative manipulator is able

to foresee collisions, and when it detects an unexpected object, it stops its movements to avoid the collision. Human operators may not understand why the manipulator has stopped its movements, misunderstanding its actions. To avoid these misjudgments, when the manipulator foresees the collision, the 3D sphere starts blinking to highlight the intentions of the industrial robotic arm. Finally, errors due to overloading problems suddenly stop the movements of the manipulator. When this type of fault occurs, a 3D anvil, along with a warning signal, is superimposed on the payload.

Mediated reality; Mixed reality; Real-time augmentation

Definition

Augmented reality for maintenance is a technologic solution encompassing both software and hardware resources with the aim of providing additional virtual information as a support for assisting technicians in performing complex tasks.

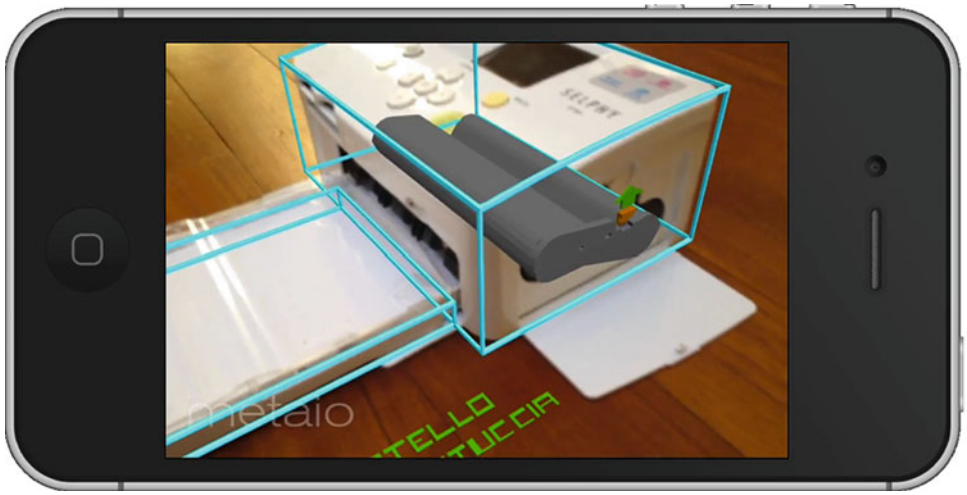
Introduction

Augmented reality (AR) is considered a computer vision solution aimed at "augmenting" the real world with additional information in the reality-virtuality continuum by Milgram and Kishino (1994). Differently from virtual reality (VR), where entire virtual reproductions of the real world are generated, in augmented reality the central idea is to add virtual objects (or overlay visual aids) into a real scene. Augmented scenes are conveyed to the user either in see-through head-mounted displays or in images captured by a camera. Computer vision algorithms have the key role of analyzing the images provided by the camera and solve the positioning and orientation problem of virtual objects within the real scene.

Augmented reality technology has been and is currently used in a wide range of application scenarios encompassing those concerning gaming, entertainment, cultural heritage, tourism, construction, education, health care, navigation, military, to name a few. Recently, this technology gained more interest also in industrial and manufacturing contexts due to the recent advances in the field. Indeed, even though maintenance, repair, and assembly are considered strategic application fields for augmented reality technologies from a couple of decades, only in recent times it has been possible to widen the development of related applications by focusing the efforts in the exploitation of consumer electronics devices. Previously, ad hoc hardware only used by specialists was developed and involved in limited experimental tests. Figure 1 shows an applicative use case which makes use of a consumer device (a smartphone or a tablet) to provide the user step-by-step instructions about the procedure for manual replacement of exhausted toner for a commercial printer. The application running on the handheld device recognizes the item subject to maintenance and provides contextualized hints by superimposing relevant animations to perform the replacement procedure.

The development of augmented reality applications in manufacturing processes represents the evolution of the industry in the digital era. Starting from seventeenth century, during the first industrial revolution, mechanical production systems as a substitute of hand production methods appeared for the first time in manufacturing processes. During the second industrial revolution, large-scale manufacturing of machine tools together with improvements in transports lead the industry to mass production methods. More recently, the introduction of information technology in the industry revolutionized again the manufacturing processes by pervading them with the digital transformation. For instance, programmable controllers and computer-based software applications added another dimension to the control capabilities of machine tools. The last epochal evolution in manufacturing concerns the switch from the introduction of information technology to the integration of cyber-physical systems, which is characterized by a higher degree of design complexity.

In this context, characterized by a trend in developing ever more complex manufacturing systems, all maintenance processes become ever more challenging, also for experienced operators.



Augmented Reality for Maintenance, Fig. 1 Augmented reality use case. Virtual animations are superimposed to the user's view through a mobile device to provide step-by-step instructions to replace internal components of a consumer device

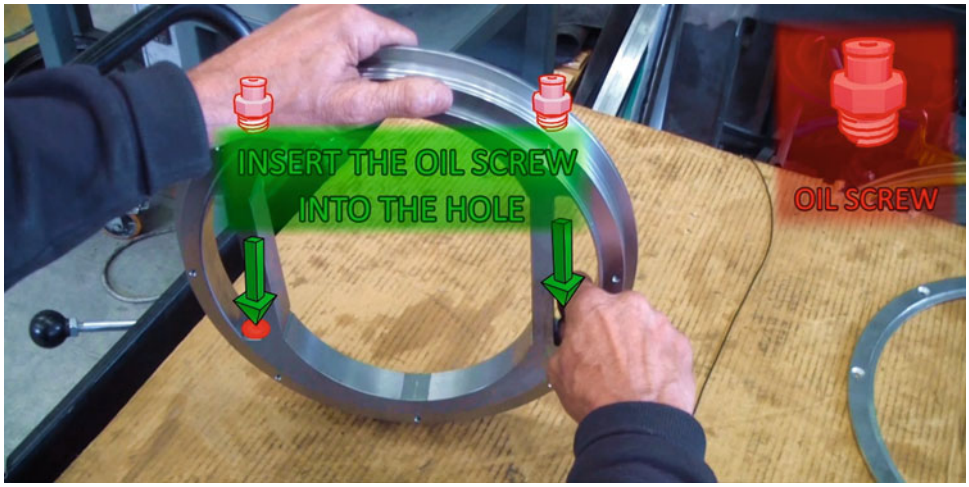
The variety of adopted industrial equipment and machinery are becoming more functionally rich. Indeed, new industrial technologies are characterized often by a combination of advanced electronics and software, thereby requiring operators to possess an in-depth knowledge which can be built only after years of work in their field. Additionally, it should be also taken into account that the fast pace of change in technology-related areas requires constant updates for the technical personnel. Often, even the more experienced operator has to deal with new situations to solve technical issues in complex cyber-physical systems. As a result, operational and functional failures are more difficult and expensive to detect, troubleshoot, and repair.

In this increasingly complex industrial machine scenario, augmented reality-based solutions aim to improve technician's performance by enabling intuitive representations and real-time visualization of relevant information regarding both corrective and predictive maintenance (Antonijević et al. 2016). Figures 2 and 3 show two applicative use cases of augmented reality in the field of maintenance in an industrial scenario, conceived in the EASE-R[12] European Project (http://www.easer3.eu/). In both cases, a technician is engaged in carrying out a specific maintenance procedure, i.e., the replacement of bearings in stone cutting machines in Fig. 2 and cleaning of lens in a laser-based precision measurement tool in Fig. 3. The illustrated use cases are representative of the main features belonging to augmented reality-based applications:

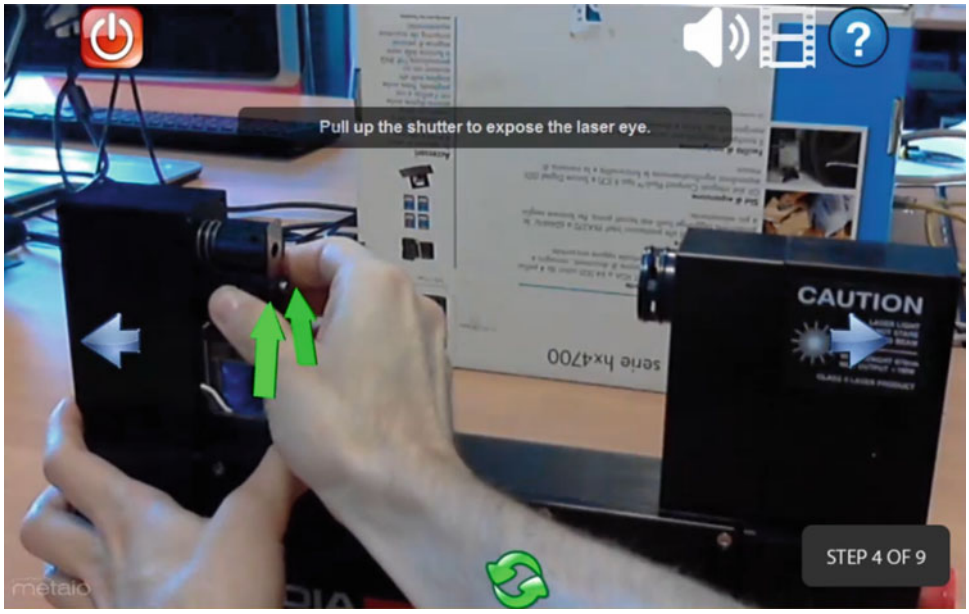
- The superimposition of virtual objects and hints onto the real world in real time
- The possibility to take into account of the user's viewpoint by means of a tracking system
- The possibility to insert virtual objects in a real world scene by automatically calculating all their 6 degrees of freedom (DOFs) which control the objects' location, orientation, and scale

Benefits of Using Augmented Reality in the Industry

Augmented reality gives the opportunity to make easier for industry workers to deal with specific industrial processes. Typical applications range from maintenance tasks, where specific and punctual information concerning cyber-physical systems are contextualized in real settings, to virtual engineering, where virtual prototypes constitute the basis for engineering tasks (Vilacoba et al. 2016).



Augmented Reality for Maintenance, Fig. 2 Augmented reality industrial use case concerning the replacement of bearings in stone cutting machines



Augmented Reality for Maintenance, Fig. 3 Augmented reality industrial use case concerning the cleaning of lens in a laser-based precision measurement tool

The most common application concern the transformation of conventional manuals into digital instructions – showing operations to be performed at the right time in the right place – which may have the characteristics of being always updated thanks to connectivity, thereby providing additional documentation available on demand and representing an effective tool for guided troubleshooting (Ghimire et al. 2016). Based on the situation faced by an operator, a visualization system – either in the form of hand-held devices (HHD) or head-mounted displays (HMD) – retrieve all necessary information and provides appropriate instructions back to the user

through the augmented reality display and other components (e.g., audio). Instructions can be of arbitrary choice, from simple reproduction of technical manuals, design diagrams, schematics to contextualized 3D static models, virtual animations, short movies, images, and audio instructions. Instructions are superimposed to the field of view of maintenance operators, which can safely work on faulty equipment.

Augmented reality can be seen as a methodology to provide just-in-time training, by delivering only the information needed in a particular context while performing a specific task. Technicians exploit this information to operate on the task and are able to increment their prior personal knowledge in a lifelong learning process. This way, they are also allowed to deal with an increased range of maintenance tasks than before with less training, which translates in evident advantages from the point of view of a more cost effective allocation of the workforce in the industry. In fact, in this scenario, a single operator is able to handle several equipment and customers' machineries, thus improving responsiveness and customer satisfaction.

It has been proven that augmented reality allows users to perform maintenance tasks with a lower rate of errors and faster than using paper-based instruction manuals (Lamberti et al. 2014, 2017; Henderson and Feiner 2011). This is due to an improved user experience driven by the fact that virtual tools can be directly shown in real working environments and real-time information is always available in the scene for the technician. It is worth recalling that faster intervention times at the factory floor reduces machinery downtime, thereby reducing loss of profits for an industry. Moreover, other key drivers for the adoption of these systems concern the reduction of technicians' mental workload during operations, the possibility to count on technical assistance during maintenance, and the reduction in training time for new technicians.

Trends and Challenges

To maximize the effectiveness and usability of augmented reality interfaces, their design should seamlessly integrate computer graphics with real environments by avoiding the use of encumbering technologies. Today, the majority of mobile augmented reality systems are based on head-mounted displays (HMDs) and see-through devices. HMDs involve the use of complex equipment to be worn by the user (e.g., the Oculus Rift). See-through systems became popular due to the rapid prototyping possibilities offered by several software libraries (e.g., ARToolkit). However, a current bottleneck is constituted by the use of transparent display technology, which is not mature yet.

There exist several options for overlapping digital contents to the surrounding world (Navab 2004):

- Projecting virtual models onto objects in the real world
- Integrating virtual models into camera views obtained from video cameras
- Projecting virtual components onto the user's retina
- Visualizing the virtual components through a semitransparent display while observing the real world

In industrial scenarios, the last two options should be preferred since they provide unhindered views while remaining safe and secure. In fact, portable and unobtrusive devices like see-through glasses guarantee hands-free operations by repair technicians.

Virtual retinal displays (VRDs) have been also recently introduced to overlay diagnostics and repair instructions directly onto the view of maintenance operators.

Whatever the technology used to visualize the augmented components, one of the key problems in augmented reality is the determination of the position and orientation of a camera in 3D space, known as camera pose estimation problem. It should be considered that the level of accuracy needed in pose estimation in augmented reality applications for maintenance is, in general, more demanding than in other fields. Indeed, small changes in a pose can be the cause of huge deviations in the visualization of the virtual content (Lakshmprabha et al. 2015).

The majority of augmented reality applications are based on the use of markers (like QR codes) to solve the real-time camera pose estimation problem (Antonijević et al. 2016). Marker-based techniques are particularly suitable for stationary objects. They require to modify the aspect of the real world manufacturing scenario by introducing specific markers on the top of machines or within the real environment to correctly locate virtual assets. Therefore, often the use of markers is perceived as a limitation of augmented reality (De Crescenzio et al. 2011). Marker-based techniques require that illumination is sufficient and markers are always visible.

On the other hand, marker-less techniques permit both to track moving parts and avoid the use of external markers to be placed in the environment (Lamberti et al. 2017). Marker-less techniques are based on image processing algorithms aimed to detect image features and perform 3D reconstruction. The process involves different phases, namely feature extraction, features detection, features matching, and image registration. The most promising algorithms used for feature extraction are Scale Invariant Feature Transform (SIFT) and Speed-Up Robust Features (SURF). Features detection algorithms apply classification mechanism like Support Vector Machine (SVM), K-Nearest Neighbor (KNN), and Sparse Representation-based Classification (SRC). Features matching, which consists in finding the correspondence between two set of features, can be achieved by applying the well-known k-d Tree algorithm. Finally, Image Registration concerns the calculation of the geometrical transform that aligns the featured points of two images of the same object. A suitable methodology is provided by random sample consensus (RANSAC) (Dandachi et al. 2015).

Given the overview of the algorithms used in augmented reality, a possible bottleneck concerns the need of sophisticated processing on devices that should be portable. The challenge is to develop solutions capable to take into account the currently achievable speed and accuracy. In fact, one of the issues with today's augmented reality applications is the lack of accuracy in 3D resolution (Vilacoba et al. 2016), which translates into a problem in precise positioning of virtual components.

Additional challenges are raised by the interaction paradigm needed for using the application effectively and in natural way. Though many augmented reality applications are developed just as an informative means (e.g., furniture placement in interior design), thus letting the interaction through touch-based screen devices be suitable for the specific task, the use cases which can be faced in manufacturing and industrial scenarios have different requirements in terms of interaction. In fact, technicians should carry out hands-free tasks. This requirement makes troublesome the use of input devices based on hand interaction, e.g., touch- and multitouch-based. A possible solution is related to the use of speech recognition technology, today enough mature to ensure an intuitive and natural user experience. Recent proposals in the field encompass also the possibility of automatically generating icon-based interfaces to associate unconstrained voice commands issued by the user to application functionalities based on the semantic similarity with the evoked command (Lamberti et al. 2017). However, it should be considered that speech recognition technology is robust in controlled situations, i.e., non-noisy environments. Thus, the noise at the factory floor should be taken into account in the design of an augmented reality solution. Gaze-based communication represents a possible alternative solution to the problem of hands-free interaction. Gaze recognition provides a thoughtful and natural interaction mode. On the other hand, special purpose hardware (i.e., infrared cameras) is needed to realize a robust gaze-based interface, which can be in competition with the hardware used for augmented reality (e.g., HMD and see-through glasses). Other possible solutions concern the use of gesture/pose recognition technologies, where the user could interact with the application interface both by using hand gestures/static poses (e.g., recognized through consumer devices such as the Leap Motion and Microsoft Kinect) and wearable solutions (e.g., inertial-based trackers) Henderson and Feiner (2010). However, in all these latter cases, the technician should suspend the maintenance procedure to interact with the application.

Conclusion and Discussion

Augmented reality domain can be applied in different application scenarios, encompassing gaming, entertainment, cultural heritage, tourism, construction, maintenance, education, health care, navigation, and military. Among them, industrial maintenance and repair represents a strategic thread for the application of augmented reality-related technologies, due to the economic revenues resulting from the possible reduction in time required for maintenance of complex systems and the automation of training processes. This entry described the benefits of using augmented reality technologies in the maintenance and repair field. Open issues are also discussed, mainly focusing on technological problems that currently limit a further spread of augmented reality solutions.

Augmented Reality in Image-Guided Surgery

Fabrizio Cutolo
Department of Information Engineering, University of Pisa, Pisa, Italy

Synonyms

Augmented reality in surgery; Image-guided surgery; Surgical navigation

Definition

Augmented reality visualization in image-guided surgery provides the surgeon with the ability to access the radiological images and surgical planning contextually to the anatomy of the real patient. It aims to integrate surgical navigation with virtual planning.

Introduction

The general ability to see into a living human system and to transfer the three-dimensional complexity of the human body into a comprehensive and useful visual representation has historically been considered of utmost importance by physicians in their will to pass on the acquired knowledge and experience to future generations (Fig. 1). In more recent times, the growing availability of new medical imaging modalities together with the need to reduce the invasiveness of the surgical procedures has encouraged the research for new 3D visualization modalities of patient-specific virtual reconstructions of the anatomy. Those visualization modalities have been designed to act as surgical guidance and as tools for surgical planning or for diagnosis (Peters 2000, 2006).

The idea of integrating in situ the surgeon's perceptive efficiency with the aid of new augmented reality (AR) visualization modalities has become a dominant topic of academic and industrial research in the medical domain since the 1990s. The high expectations accrued among researchers, technicians, and physicians regarding this fascinating new technology were predominantly related to the improvements potentially brought by AR-based devices to surgical navigation and planning. In this context, AR visualization is indeed regarded as capable of providing the surgeon with the ability to access the radiological images and surgical planning contextually to the real patient anatomy.

Consequently, in image-guided surgery (IGS) systems, AR technology appears as a significant development, because it aims to profitably integrate surgical navigation with virtual planning (Kersten-Oertel et al. 2013).

Augmented Reality in Image-Guided Surgery, Fig. 1 Pictorial representation of the th7ree-dimensional complexity of the human anatomy (Frans Denys, The Anatomy Lesson of Dr. Joannes van Buyten, 1648, oil on canvas)

State-of-the-Art Work

Background

In 1986 (Roberts et al. 1986) a first implementation of a medical AR neurosurgical guidance system was proposed: the system was intended to allow the proper projection of computed tomography (CT) image data into the optics of an operating microscope. After an interactive patient-to-CT image registration, an ultrasonic non-real-time tracking of the microscope allowed proper reformatting of the CT data before being projected into the eyepieces of the microscope. Since then, tools (or defined applications) employing AR have been designed and tested in the context of several surgical and medical disciplines (Rankin et al. 2015). These applications comprise video see-through systems (in conjunction with standard workstations, laptops, and tablet PC), modified endoscopes, and modified operating microscopes. AR has been proposed in many surgical contexts, including maxillofacial surgery (Marmulla et al. 2005; Zinser et al. 2013b; Badiali et al. 2014; Suenaga et al. 2015; Wang et al. 2017; Zhu et al. 2017), neurosurgery (Edwards et al. 2004; Lovo et al. 2007; Low et al. 2010; Inoue et al. 2013; Cabrilo et al. 2014, 2015; Kersten-Oertel et al. 2015; Meola et al. 2016; Cutolo et al. 2017), ENT (ear, nose, and throat) surgery (Caversaccio et al. 2008), orthopedic surgery (Navab et al. 2010; Abe et al. 2013; Wu et al. 2014; Fritz et al. 2014; Cutolo et al. 2016a; Elmi-Terander et al. 2016), robotic surgery (Falk et al. 2005; Su et al. 2009; Zeng et al. 2017), and general/laparoscopic surgery (Feuerstein et al. 2008; Baumhauer et al. 2007; Nicolau et al. 2011; Muller et al. 2013).

Open Issues

Despite such widespread diffusion, there are still major reasons why AR IGS systems are not yet routinely used in the medical workflow. Among them, there is the fact that most of the systems were historically, and still are, developed as proof-of-concept devices that were/are mostly conceived for research users more than for their immediate translation into immediate and reliable applications.

Many of those systems did not take into account the operational constraints imposed by the surgical context and did not satisfy the surgeons' practical needs and requirements. Generally, many AR systems have been regarded as disrupting the surgeon's act primarily because most of them have lacked of a systematic evaluation within a clinical context (Kersten-Oertel et al. 2012; Meola et al. 2016). In fact, the basic condition for the acceptance of a new technology (as AR) in the operating room (OR) is related to its capacity of being smoothly integrated into the workflow of the intervention, without affecting and disturbing the user during the rest of the procedure (Navab et al. 2007; Sielhorst et al. 2008).

Despite all of this, with the advances in technology, AR will surely soon represent a leading-edge solution in the context of IGS, especially once the balance between technological expectations and realistic and application-driven outcomes will be achieved.

Taxonomy for Classification

In 2012, a taxonomy of AR visualization systems in IGS was proposed (Kersten-Oertel et al. 2012), and a systematic overview of the trends and solutions adopted in the field to that day presented (Kersten-Oertel et al. 2013). The acronym for the taxonomy (DVV) is derived from its three key components: data type, visualization processing, and view. According to the taxonomy, for classifying and assessing the efficacy of a new AR system for IGS, the attention ought to be focused on the particular surgical scenario in which the visualization system aims to be integrated.

The surgical scenario affects each of the three DVV factors, namely, the type of data that should be displayed at a specific surgical step, the visualization processing technique implemented to provide the best pictorial representation of the augmented scene, and how and where the output of the visualization processing should be presented to the end user (i.e., the view).

Different AR Display Units in IGS

In the realm of AR-based IGS systems, different technological approaches and specifically different embodiments of the display units have been proposed, each with its own advantages and drawbacks. In Table 1 advantages and drawbacks of different AR-based solutions are reported. In the light of avoiding abrupt changes to the surgical setup and workflow, historically the first AR-based systems in surgical navigation have been implemented starting from commonly used devices. Augmented operating microscopes were proposed in neurosurgery and in maxillofacial surgery (Birkfellner et al. 2002). In these systems, generally the augmentation happens by "injecting" the virtual content directly into the optical path of the real image, hence by inserting a beam splitter into the microscope optics. The fixed configuration of the eyepieces with respect to the surgical scene makes them not usable with different viewpoints.

Other solutions featured the use of spatial monitors and video-based tracking modalities and were used in neurosurgery (Grimson et al. 1996; Deng et al. 2014), maxillofacial surgery (Zinser et al. 2013a), and general surgery (Muller et al. 2013). Such systems, as the ones based on external monitors, have a reduced logistic impact within the operating room, but they do not provide an egocentric viewpoint of the surgical scene.

Another category of AR systems was based on the use of half-transparent screens in conjunction with display technologies providing monoscopic, stereoscopic, or autostereoscopic parallax. Blackwell (Blackwelll et al. 1998) and Wesarg (Wesarg et al. 2004) introduced two different prototypes of AR windows. The first system by Blackwell provided a stereoscopic vision of the virtual content by means of a pair of shutter glasses, whereas the second one by Wesarg was monoscopic. Stetten et al. (2001) have proposed a simple and interesting optical see-through handheld half-silvered mirror that overlays ultrasound scans aligned with the scanned area.

The major shortcomings of the optical see-through paradigm implemented in standard AR windows are due to the intrinsic incompatibility between the 3D representation of the real world and the nature of the virtual content, rendered as a 2D image. This causes few perceptual conflicts in depth perception. To cope with these issues, alternative and promising approaches, based on the integral imaging technology, were proposed (Liao et al. 2001, 2004). Integral imaging displays use a set of 2D elemental images from different perspectives to generate a full-parallax 3D visualization. Therefore, with integral imaging-based displays, a proper 3D overlay between virtual content and real scene can be obtained. Some embodiments of such technology have been specifically designed and tested for maxillofacial surgery and neurosurgery (Iseki et al. 1997; Narita et al. 2014; Liao et al. 2006, 2010; Suenaga et al. 2013). The integral imaging paradigm thus is able to provide the user with an egocentric viewpoint and a full-parallax augmented view in a limited viewing zone (imposed by the integral imaging display).

In laparoscopy, and generally in endoscopic surgery, the part of the environment where the attention of the surgeon is focused during the surgical task (DVV's perception location) is a stand-up monitor. Indeed, in such procedures, the surgeon operates watching endoscopic video images reproduced on the spatial display unit (Caversaccio et al. 2008; Freysinger et al. 1997). Therefore, the virtual information is usually merged with the real-time video frames grabbed by the endoscope and presented on a stand-up monitor. These systems were also tested in robotic surgery (Su et al. 2009; Mourgues and Coste-Maniere 2002; Devernay et al. 2001). Particularly in IGS, the quality of an augmented reality (AR) experience depends on how well the virtual content is integrated into the real world spatially, photometrically, and temporally (Sielhorst et al. 2008). For this reason, wearable AR systems particularly offer the most ergonomic solution in those medical tasks manually performed under user's direct vision (open surgery, introduction of biopsy needle, palpation, etc.) since they minimize the extra mental effort normally required for switching the attention between the surgical area and the augmented view presented on the external display.

Augmented Reality in Image-Guided Surgery, Table 1 Different embodiments of AR displays for IGS

AR display type	Advantages	Drawbacks
Surgical microscope	Surgical microscopes are already routinely used in several microsurgical procedures	Bulkiness
	Fixed configuration: degradation of the calibration is decreased	Fixed configuration: not adaptable to comply with different viewpoints
Video see-through handheld displays (tablet-smartphones)	Reduced logistic impact	Parallax problem (non-egocentric viewpoint)
		No stereopsis. Other depth cues are needed for depth perception
	Accurate image registration – no eye-to-display calibration is needed	Difficult to use in those surgical tasks manually performed under surgeon's direct vision
		Peripheral view not registered with AR view
		Camera-mediated view of the surgical area
Optical see-through external screens (stereoscopic and monoscopic)	Direct view of the surgical area	AR image registration is not so accurate: robust and reliable eye-to-display calibration would be needed
		Display brightness may not be sufficient under scialytic lamps
		Perceptual conflicts due to mismatched accommodations between real scene and virtual content
		Parallax problem (non-egocentric viewpoint)
		Difficult to use in those surgical tasks manually performed under surgeon's direct vision
Video see-through external displays	External monitors are already present in the surgical rooms	Parallax problem (non-egocentric viewpoint)
		Mostly 2D displays: no stereopsis
	Accurate image registration – no eye-to-display calibration is needed	Difficult to use in those surgical tasks manually performed under surgeon's direct vision
		Camera-mediated view of the surgical area
Full-parallax 3D displays	Full-parallax view of the scene. Natural depth perception is recovered	Bulkiness
	Accurate image registration – no eye-to-display calibration is needed	Limited depth range
		Limited resolution and limited viewing zone
Optical see-through wearable displays (monoscopic or stereoscopic)	Egocentric viewpoint	Perceptual conflicts due to mismatched accommodations between real scene and virtual content
	Reduced logistic impact	AR image registration is not so accurate: robust and reliable eye-to-display calibration would be needed
		Display brightness may not be sufficient under scialytic lamps
Video see-through wearable displays (monoscopic or stereoscopic)	Egocentric viewpoint	Perceptual vergence-accommodation conflict
		Restricted peripheral view
	Accurate image registration – no eye-to-display calibration is needed	Surgeon's field of view is restricted by the display
	Reduced logistic impact	Camera-mediated view of the surgical area

Wearable AR Displays in IGS

Wearable AR systems based on HMDs intrinsically provide the user with an egocentric viewpoint, and by generating both binocular parallax and motion parallax, they smoothly augment the user's perception of the surgical scene (Cutolo et al. 2016b). In these HMDs, the see-through capability is accomplished either through the aforementioned video see-through paradigm or through the optical see-through paradigm.

Typically, in optical see-through systems, the user's direct view of the real world is augmented with the projection of virtual information on a beam combiner and then into the user's line of sight (Rolland et al. 1994). Differently, in video see-through systems, the virtual content is merged with camera images captured by two external cameras rigidly fixed on the visor.

The industrial pioneers, as well as the early adopters of AR technology, properly considered the camera-mediated view typical of the video see-through paradigm, as drastically affecting the quality of the visual perception and experience of the real world. By contrast, optical see-through systems provide the user with a natural view of the real world with full resolution. The fundamental optical see-through paradigm of HMDs is still the same as described by Benton (Benton 2001). A straightforward implementation of the optical see-through paradigm comprises the employment of a half-silvered mirror or beam combiner to merge real view and virtual content. The user's own view is herein augmented by rendering the virtual content on a two-dimensional (2D) microdisplay and by sending it to the beam combiner. Lenses can be placed between the beam combiner and the display to focus the virtual 2D image so that it appears at a comfortable viewing distance on a semitransparent surface of projection (SSP) (Rolland and Cakmakci 2005; Holliman et al. 2011). As an alternative, the use of high-precision waveguide technologies allows the removal of the bulky optical engine placed in front of the eyes (Mukawa et al. 2008). The optical see-through paradigm is particularly suitable for augmenting the reality by means of simple virtual elements (models, icons, or text labels), but shortcomings remain both from a technical and a perceptual standpoint, especially in case of virtual contents of greater complexity.

Although the optical see-through HMDs were once at the leading edge of the AR research, their degree of adoption and diffusion did slow down over the years due to technological and human-factor limitations. Just to mention a few of them: the presence of a small augmentable field of view, the reduced brightness offered by standard LCOS microdisplays, the perceptual conflicts between the 3D real-world and the 2D virtual image on the SSP, and the need for frequent recalibrations of the HMD for yielding accurate spatial registration. Some of the technological limitations, like the small field, are being and will be likely solved along with the technological progress. The remaining two limitations are harder to cope with.

The difference in the user's perception of the real 3D world and of the 2D projection of the virtual content on the SSP creates perceptual conflicts due to mismatched accommodations. These perceptual conflicts often are reflected in reducing the benefits brought by the optical paradigm of leaving unaltered the user's view of the real world. In optical see-through HMDs, the user is indeed forced to accommodate his/her eye for focusing all the virtual objects on the SSP placed at a fixed distance. On the other hand, the focus distance of each physical object in the 3D world depends on its relative distance from the observer and may dynamically vary over time. This means that even if an accurate geometric registration of virtual objects to the real scene is attained on the 2D SSP plane, the user may not be able to view both the virtual and real content in focus at the same time. This aspect is particularly relevant in applications devoted to surgical navigation, since it reduces the user's capacity to interact with the real surgical field while maintaining the virtual aid in focus. The second major shortcoming of the standard optical see-through HMDs is related with the geometric registration required to obtain a geometrically consistent augmentation of the

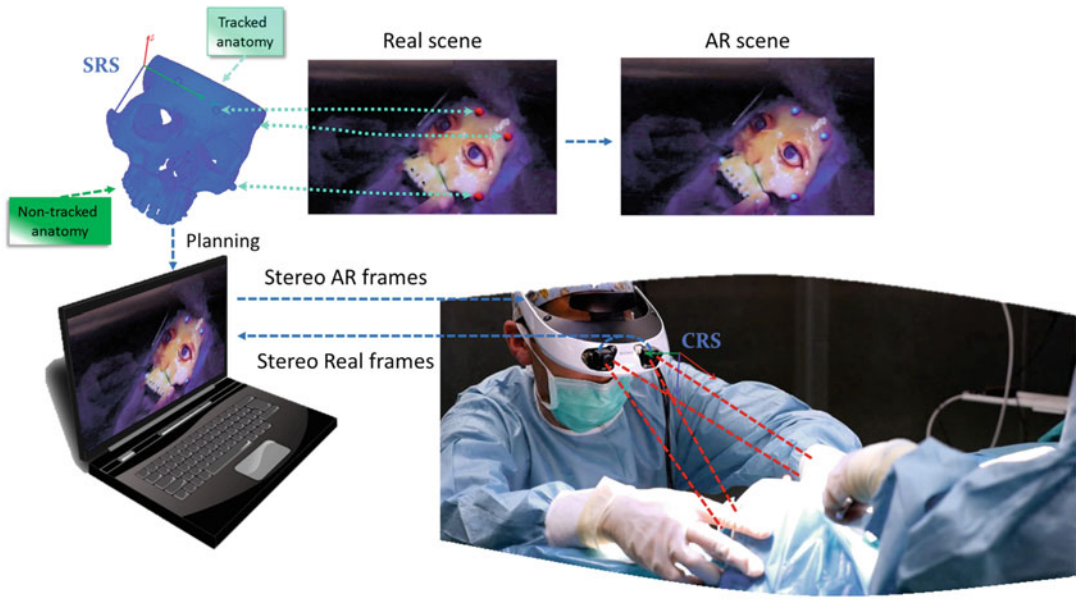
reality, which is an essential prerequisite for being considered as reliable surgical guidance system.

As a general rule, for obtaining accurate geometric registration in AR applications, the process of image formation generated by the virtual viewpoint must perfectly mimic, both intrinsically and extrinsically, the one of the real viewpoint (Cutolo et al. 2014). In optical see-through HMDs, the spatial alignment of the virtual content with the real 3D world needs for:

(a) The tracking of the HMD SSP in relation to the reference system of the real world (SRS)
(b) A user-specific calibration for estimating the pose between HMD SSP and user's eye (i.e., extrinsic calibration)
(c) The definition of a projective model of the virtual viewpoint that is consistent to the human eye projective model (i.e., intrinsic calibration)

State-of-the-art methods for tracking the HMDs (a) yield accurate results in terms of HMD pose estimation, whether they exploit external trackers or not. Differently, the calibration step needed to estimate user's eye pose in relation to the SSP reference system (b) often entails a tedious and error-prone method (Tuceryan et al. 2002; Genc et al. 2002; Gilson et al. 2008; Kellner et al. 2012). Further, this process should be repeated any time the HMD moves with respect to the user's eyes causing a change in the relative position between DRS and user's eye reference system, and it should be autonomous and real time. Current and more advanced calibration methods (Plopski et al. 2015, 2016), even if they work in real time, do not incorporate the user-specific and real-time estimation of the eye projective model (c), which can change over time with the focus distance due to the accommodation process.

Differently, the pixel-wise video-mixing technology that underpins the video see-through paradigm, once integrated with monocular or binocular HMDs, can offer high geometric coherence between virtual and real content. In these systems, a user-specific calibration routine is not necessary, and this is the major advantage of the video versus the optical see-through approach. In video see-through systems, real scene and virtual information



Augmented Reality in Image-Guided Surgery, Fig. 2 Video see-through paradigm of the stereoscopic HMD used to aid maxillary repositioning (Cutolo et al. 2015)

can be synchronized, whereas in optical see-through devices, there is an intrinsic lag between the immediate perception of the real scene and the inclusion of the virtual elements. Further, from a perceptual viewpoint, in video see-through systems, the visual experience of both the real and virtual content is unambiguously controllable by computer graphics, with everything on focus at the same apparent distance from the user. Additionally, video see-through systems are much more suited than optical see-through systems, to rendering occlusions between real and virtual elements or to implementing complex visualization processing modalities. Unfortunately, the loss of the unobstructed real-world view and the limited field of view of the displays embedded in commercial 3D visors are still the major drawbacks of the video see-through HMDs (Fig. 2). This aspect is of particular importance in IGS applications, wherever our goal is of trying to mimic the perceptive efficiency of the human visual system to allow a smoother interaction with the augmented visual information (Cutolo et al. 2015).

Conclusions and Future Goals

In recent times, the emerging of modern medical imaging technologies together with the need to reduce the invasiveness of the surgical procedures has encouraged the research for new 3D visualization modalities that could act as tools for surgical guidance. Current limits of standard IGS systems are mainly due to the increase of the surgical time needed for system setup and management and to the increase of technical complexity in the surgical workflow.

It was thus clear from the outset that, in this context, AR technology could have represented a groundbreaking development, because its primary goal is to integrate surgical navigation with virtual planning contextually to the real patient's anatomy.

AR technology can in fact provide the surgeon with a direct perception of where the virtual content is located within the surgical field, wherever the virtual content is generally obtained during preoperative planning.

In the ideal AR system, especially if designed for aiding complex operations that demand great dexterity as the ones pertaining to surgical procedures, there should not be any perceivable difference between the user's natural view of the world and his/her augmented view through the device display. For this goal, the conditions to be satisfied are twofold: accurate registration and ergonomic interaction.

In practical terms, if a new AR system for IGS were to comprise tedious calibration routines, the introduction of obtrusive instrumentation into the OR, and the presentation of complex and confounding computer-generated content and furthermore it were to bring questionable benefits to the surgical procedure, then it would be likely refused. Hence, to facilitate the accomplishment of such ambitious goals in the near future, researchers and early adopters ought to actively collaborate with physicians so that AR-based IGS systems could smoothly and profitably get into the surgical workflow.

Definition

An autonomous agent works with artificial intelligence (AI) to decide its actions to adapt and respond to the changes in a dynamic environment. The autonomous agent can be developed in games as a non-player character to interact with the changes of state in the game environment. Traditional board games such as Ludo have had many players since olden days but have slowly lost attraction to the public, especially the younger generations, as digital games become more popular. Although the Ludo board game can be digitized to fascinate the players through implementing augmented reality (AR) technology on handheld devices, common NPCs found in games have predetermined actions and are unable to learn from experience and adapt to the changes in the game environment. AR Ludo board game with Q-learning applied in handheld.

Introduction

Board games have appeared since ancient times with a lot of experienced players (ChePa et al. 2014). An example of a popular traditional board game is Ludo (Singh et al. 2019). However, the number of traditional board game players has declined since the appearance of digital games (Rizov et al. 2019). Hence, the Ludo board game can be digitized to retain the existing players while attracting new players.

Augmented reality (AR) is a technology that combines the real environment with the virtual environment or objects created by a computer (Tan and Soh 2011). This technology is added to a board game to further enhance the gaming experience (Rizov et al. 2019). Nowadays, AR technology is widely used in handheld devices such as smartphones that are equipped with advanced features (Zsila et al. 2018). Sensors that can be used to capture image, movement, and touch are equipped by the handheld devices (Grandi et al. 2018) as the rise of the devices' computational power (Sanches et al. 2019).

An autonomous agent is an agent that can decide to perform an action by itself in a given environment (Coutinho et al. 2015). The development of an autonomous agent is often tightly linked to artificial intelligence (AI), especially on decision-making (Moharir et al. 2019). In games, a non-player character (NPC) can act as an autonomous agent (Feng and Tan 2016). Common NPCs found in games are usually scripted with specific actions and are unable to learn from previous actions and adapt to a dynamic environment (Lim et al. 2012). Hence, the autonomous agent can be developed in a game through a machine learning algorithm to adapt to the changes in the environment, besides increasing the difficulty of the game and making it enjoyable (Feng and Tan 2016). Q-learning is an example of a reinforcement learning algorithm under machine learning that allows the agent to explore the environment and learn the best action in a specific state (Lee et al. 2017). The Q-learning algorithm is commonly used in a dynamic environment that involves one or multiple players [13]. Hence, the autonomous agent that works with the Q-learning algorithm can be developed for the AR Ludo board game.

AR is defined as a technology that combines real and virtual contents in the physical environment (Tan and Soh 2011). This technology overlays

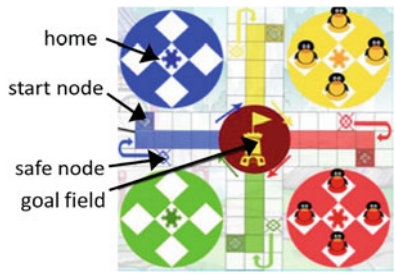
digital data on the real environment to present various information such as text or images [14]. An AR system focuses on four domains: sensing, tracking, interaction, and display [15]. An example of a tracking technique is feature-based tracking provided by Vuforia Engine to detect, identify, and track targets such as images or three-dimensional (3D) objects [16]. According to [17], Vuforia analyzes and detects the features of an image uploaded by a user. The more features detected in an image, the more suitable it is to be used as the image target. The analyzed result is represented through a star rating range from 0 to 5. The highest rating indicates that it is the easiest for Vuforia to track the image target.

Ludo Board Game

A board game is defined as a game that involves a board that allows pieces to move on top of it [18]. According to (Singh et al. 2019), the Ludo board game involves 2–4 players taking turns to roll a dice and move the tokens on the Ludo board. Figure 1 shows the Ludo board game.

The rules for the Ludo board game, as in Fig. 1, are based on [19]:

- At the beginning of the game, the players take turns to roll the dice and a player that rolls a six can move a token to the start node. Each player has four tokens at the beginning of the game.
- The players can only move a token according to the number rolled if the token is not at the home.
- Once a player rolls a six, that player can take another turn.



Augmented Reality Ludo Board Game with Q-Learning on Handheld, Fig. 1 Ludo board game [19]

- If a player moves a token to the place that is occupied by the opponent's token, the opponent's token is kicked and returned to his home.
- A token is safe from being kicked back to home once it lands on the safe square. Each player's start node is also considered as a safe square.
- The game ends once all the tokens of a player have landed on the goal field.

The development of autonomous Agent A starts with designing an algorithm based on Q-learning as in Fig. 2. Based on Fig. 2, the algorithm starts from initialization of the values in the Q-table to zero. After Agent A takes a turn to roll the dice, Agent A can select a random action through exploration or choose a greedy action through exploitation based on the epsilon-greedy (ε-greedy) policy. A greedy action is an action with the highest value in the Q-table at the given state. The epsilon value, ε, is declared as 1.0 at the beginning and continuously decreases for each action taken by Agent A. Random action is taken if the randomly generated value ranges from 0 to 1 is smaller than ε; otherwise, the greedy action is taken. The reward, r, is then measured based on the state-action pair taken. Bellman equation, $Q(s,a) = Q(s,a) + \alpha\,[r + \gamma\,[\![\max]\!]_{(a^{\wedge\prime} \in A)}\, Q(s^{\wedge\prime},a^{\wedge\prime}) - Q(s,a)]$, is used to update the value of the state-action pair taken in the Q-table. The learning rate, α, and discount factor, γ, are set as 0.7 and 0.1, respectively. These steps are repeated until the end of an episode. The training session is set up for Agent A with 20 episodes. An episode is ended once all the four tokens of a player have successfully moved into the goal field.

AR Ludo: Augmented Reality Ludo Board Game

The Ludo board game consists of a dice and four sets of tokens to match the four different colors of the home at each corner on the board. However, only two sets of tokens are used for the AR Ludo board game, as the game is limited to two players.

Augmented Reality Ludo Board Game with Q-Learning on Handheld, Fig. 2 Q-learning algorithm in Ludo board game

Initialize Q(s, a), $\forall s \in S, \forall a \in A$

For episode = 1,2,3…do

Repeat

Roll dice

For each token of the player

Initialize current state, *s*

Store s in the array

Initialize action, *a* based on the state and dice number

Store *a* in the array

End For

Choose action, *a* using epsilon-greedy policy:

If a random value < epsilon, ε

Then choose a random action, a

Else

Choose an action, a with highest Q(s,a) value

Take action, *a*

Observe reward, r and next state, s'

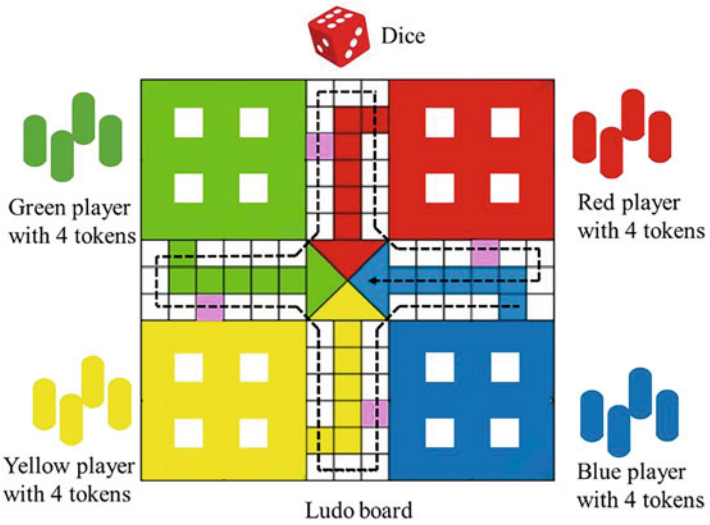
Update Q-table with Bellman equation

$$Q(s,a) = Q(s,a) + \alpha\,[r + \gamma\, max_{a' \in A} Q(s',a') - Q(s,a)]$$

Until *s* is terminal // 4 tokens of a player reach goal field

End For

Augmented Reality Ludo Board Game with Q-Learning on Handheld, Fig. 3 AR Ludo game design



At the beginning of the game, one player is assigned with the four blue color tokens; meanwhile, the opponent player is assigned with the four green color tokens. Each player's four tokens are placed in the home. Next, each player takes a turn to roll the dice to move a token from the start node into the goal field. The goal of the game is to move all the four tokens into the goal field located

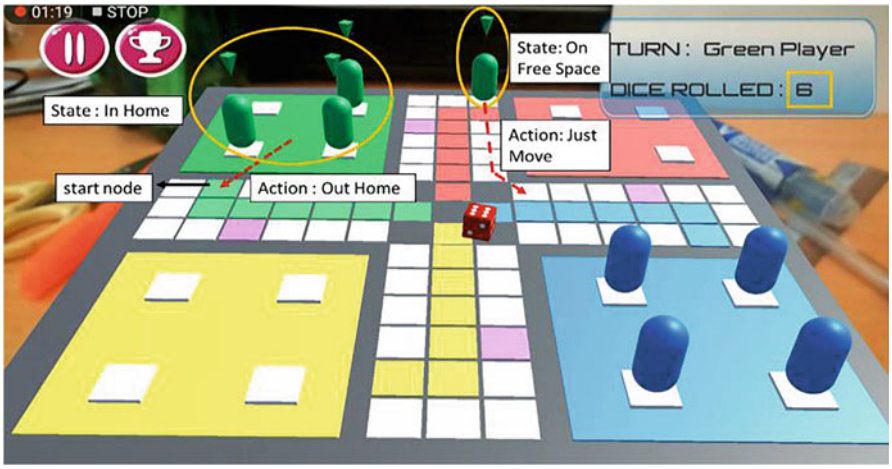
at the center of the board to win the game. Based on Fig. 3, there are four purple color nodes on the board called safe nodes and the dotted line shows an example of a blue tokens' path from the start node towards the goal field.

In order to implement the AR tracking in a handheld device, the Vuforia AR software development toolkit (SDK) is integrated with Unity3D software to track and compare the features of the marker with the target resource database. A PNG image based on the design of the Ludo board in RGB is uploaded to Vuforia Target Manager. This image is transformed into grayscale and the features extracted are collected and stored in the database. The virtual AR Ludo board game is displayed once the marker is detected and the marker's features match with the data stored in the database. The AR Ludo includes badges as a gamification element to reward the players. Feature-based tracking is chosen for AR Ludo in handheld focuses on Android mobile phones. The users can interact with the application through touch-based interaction on the mobile screen using a one-finger gesture.

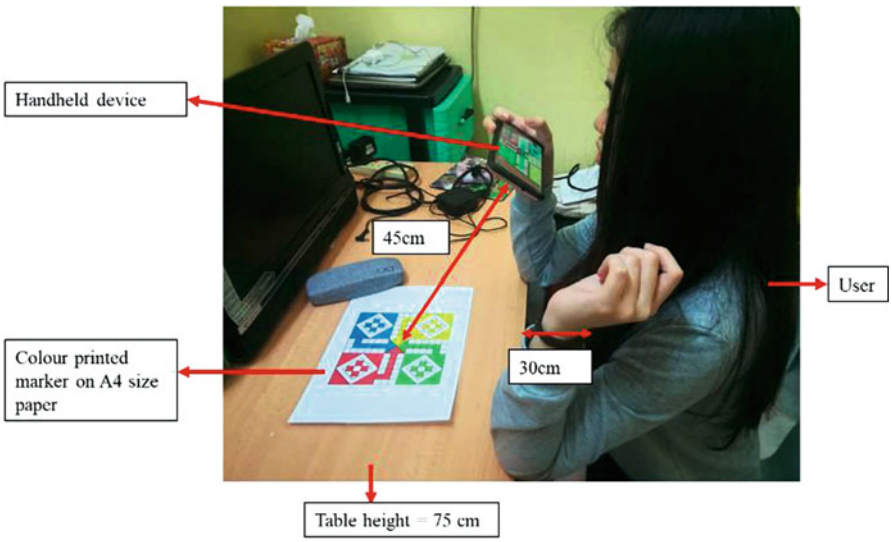
The designed Q-learning algorithm has been implemented in order to generate the optimal values in the Q-table, a training with 20 episodes is conducted between Q-learning agent (Agent A) and AR random players, and Agent A is assigned with the green color tokens. The other three random players take random actions to move in the game while training. Figure 4 shows the Ludo board game training environment performed on the Windows platform using Unity3D. The game environment is reset before starting a new episode after each episode ends.

At the end of the training, an output file that includes the finalized values of the Q-table is generated as in Fig. 5. Based on Fig. 5, the rows represent the states; meanwhile, the columns represent the actions.

An example is shown in Fig. 6 where the tokens inside the home have the state "In Home" and the action of moving a token to the start node from the home is "Out Home." A token placed on



Augmented Reality Ludo Board Game with Q-Learning on Handheld, Fig. 6 Tokens with the state "In Home" and action "Out Home" or state "On Free Space" and action "Just Move"

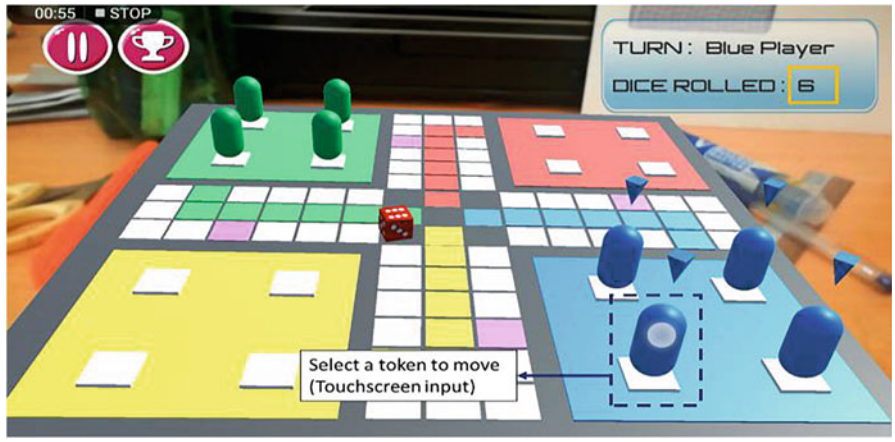


Augmented Reality Ludo Board Game with Q-Learning on Handheld, Fig. 7 User plays AR Ludo to against the Q-learning agent

a white node that surrounds the board has the state "On Free Space" and the action of moving a token from a white node to another without any opponent's token landed on it is "Just Move." Based on Fig. 6, Agent A can choose to move a token six steps forward or move a token out from home while a six is rolled. Agent A decides to move a token out of home as the value in the Q-table for this state-action is approximately 0.563 that is higher than the action "Just Move" at the state "On Free Space" with a value of approximately −1.483 based on Fig. 5.

AR Ludo on Handheld

The setup as in Fig. 7 is that the AR marker is color printed on an A4 size paper and placed on the table with a height of approximately 75 cm. The user sits approximately 30 cm in front of the



Augmented Reality Ludo Board Game with Q-Learning on Handheld, Fig. 8 AR Ludo board game on handheld

table with one hand holding the handheld device and the other hand interacting with the AR Ludo board game through touchscreen input. The handheld device with a camera used to track and display the AR Ludo board game is approximately 45 cm away from the marker.

The 3D Ludo board is developed with numerous cubes scaled in different sizes and colors of material. Each corner of the Ludo board has different colors, either yellow, blue, green, or red to represent each player's home. There are four purple color nodes that represent the safe nodes on the Ludo board, and each player's start node is set as the node that is nearest to the home with the same color. A token is created using a capsule, a 3D game object provided in Unity3D. In order to show a token can interact, an arrow model is imported into Unity3D to attach with the capsule. The dice model is also imported into the game. The UI of the AR Ludo board game is developed with buttons, checkboxes, and panels for interaction. The AR tracking is also enabled in handheld.

The AR Ludo board game allows the human player to play with the opponent player, Agent A. The human player is represented as the blue color tokens; meanwhile, the Agent A is represented as the green color tokens. On a human player's turn, the player can select the dice to roll or select a token to move as in Fig. 8 by touchscreen input after rolling a six.

Introduction

Games design is the field of study and practice of improving and measuring the structure and systems found within an analogue or digital game. The process of improving a game throughout the development and lifecycle of a game is key to the survival of the game. Notable examples include changes found within the rules of chess throughout its long lifespan and different iterations and versions of the game (Murray 2015). Game designers incrementally change the game to provide better entertainment to its participating players. Game designer and developer Robert Zubek defines game design by breaking it down into its elements, which he says are the following (Zubek 2020):

- Gameplay, which is the interaction between the player and the mechanics and systems
- Mechanics and systems, which are the rules and objects in the game
- Player experience, which is how users feel when they are playing the game

Improving a game design can be achieved through the use of analytical or experimental processes.

Paper Overview

This paper focusses on the different strategies and examples of the use of deep learning techniques when testing game design. This focusses on two aspects. A suitable use case of player replacements is to simulate experimental game design approaches such as automated play testing and content evaluation. Furthermore, this paper concludes with a brief summary of research measuring sentiment toward automated

game design testing processes by industry stakeholders.

Types of Game Design Techniques

Both analytical and experimental game design processes are resource intensive through the required analysis and participation of the player within the design process. Game publishers and academics have numerous testing approaches to accelerate the creation of games and improve the quality of their design in each part of the game lifecycle. Early attempts showed how games are controlled by procedural code such as behavior trees (Sekhavat 2017).

Large companies such as Ubisoft (Roy et al. 2022) and EA (Bergdahl et al. 2021; Sestini et al. 2022) have pioneered several approaches toward intelligent systems within the games development process allowing the assessment of games design such as automated playtesting using deep reinforcement learning agents, as well as the creation of artistic content using neural networks capable of creating state-of-the-art animation controllers that were trained using unsupervised learning techniques applied to motion capture data, proving the real-world interest in the applications of intelligent tools in games development.

Experimental Game Design

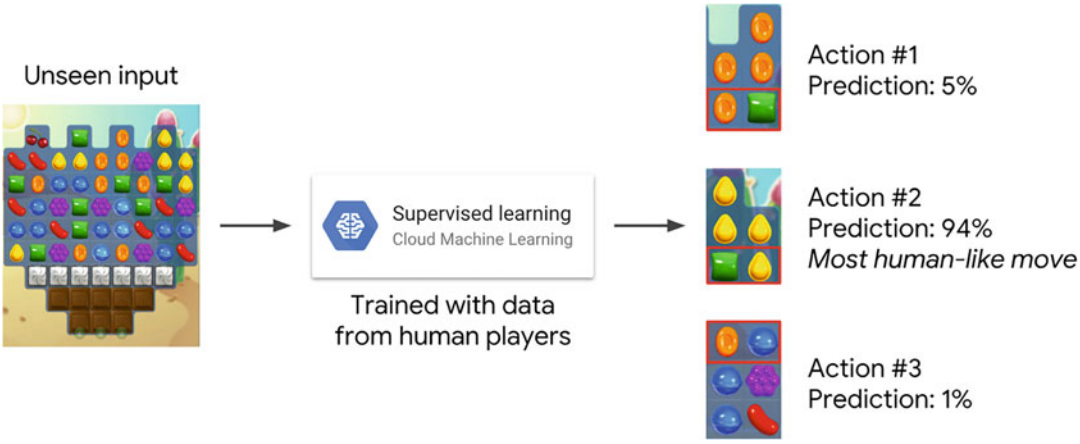
Experimental game design is immensely popular in both early development and later content updates (Waern and Back 2015). Toward the end of the development of a new game or feature, designers with programming skills focus on rapid prototyping to see how the newly created content fits within the existing content and how the implementation achieves the esthetic goals the designers have for the new feature during gameplay. Later within the development cycle of the game, publishers can create experimental versions of the game that players can opt-in to try and explore. This allows designers to test new features on a live player base that is aware that they may experience uncompetitive and less polished experiences, with the benefit being that they are early adopters and will be more prepared when the changes are moved to the live game environment. Through experiments, designers can collect qualitative and quantitative data, which they can use to make informed choices about the trajectory and changes that will be made to the game.

Analytical Game Design Improvements

Analytical design improvement is through the collection and comparison of numbers from game elements directly from the game content, such as weapon parameters or gameplay metrics generated from players playing the game. Using techniques such as cost curve analysis, game designers can accurately measure the fairness and effectiveness of all the content available from the game. Tools and techniques to evaluate the validity of game parameters have evolved over the years. A new addition to the game designer tool belt are machination diagrams, a visual-graph-based language allowing designers to test the design of different game systems (Adams and Dormans 2012). Analytical methods follow a reductive process that allows designers to see the impact of changes immediately within the games' internal systems. Cost curve analysis lists every mechanic and item within a modern game as an item with a benefit and a cost. As the benefit of an item increases, so does the cost Carpenter (2003) value. Designers place the cost increases of an item in line with the benefit of a game, mechanic, or resource, and each item within the world has been referred to as *Jedi Curve* within *Magic The Gathering* Credits (2012). The cost–benefit relationship between each item forms the shape of the curve. During the balancing process, a designer can use it to see where a specific component of the game fits within the system. Small imbalances are allowed, as choosing the most efficient or effective item creates interesting decisions for the players to choose from.

Player Replacements

This section outlines the different approaches to implementing player replacements, which can generate gameplay data for use in automated



Automated Game Design Testing Using Machine Learning, Fig. 1 Crush Saga: Deep Learning AI (Gudmundsson et al. 2018)

playtesting and experimental game design workflows. Player replacements refer to the use of artificial intelligence agents that simulate the player playing the game, making conventional and advanced game testing easier and faster.

New approaches have been proposed to test the design and balance of video games to improve iteration time and precision using automation, and replacements for players have been proposed. Notable examples have been proposed by the AAA games studio *King Entertainment* publisher of the popular "Crush Saga" games. King researched the evaluation of match-3 level design through predicted play test results using machine learning techniques (Gudmundsson et al. (2018) shown in Fig. 1). *Electronic Arts (EAs)* have recently proposed a framework for testing their games using learning agents to accurately reflect the goals of designers and the demographics of the players found in each game (Zhao et al. 2019). Academic organizations and researchers have proposed a broad variety of ideas for how artificial intelligence (AI) can help game designers create games by treating game balance as an optimization problem and using AI to reduce the possible search space, an example of this is by parameter tuning a game "*Shoot 'Em Up"* using active learning techniques (Zook et al. 2019). Another paradigm to accelerate the creation and testing of games that has received attention in academic research is to consider game design or player behavior as a problem domain for reinforcement learning, such as having learning agents design levels (Zhang et al. 2017; Khalifa et al. 2020) or using cutting-edge reinforcement learning algorithms designed to emulate player behavior to generate gameplay data by simulating the game being played (Holmgård et al. 2014; Holmgård et al. 2015). Previous research has shown real progress in testing single-player games. Minimal research has been conducted on the use of machine learning techniques to accelerate the design process of multiplayer games.

Researchers have shown how mathematical representations of simple games can be used to assess the difficulty of the game for different demographics of players (Lee et al. 2021). Research was carried out on target–movement games, which are a popular genre for mobile games that include **Flappy Bird** and **Temple Run**. Evaluating the difficulty is possible by collecting cognitive data from specific player bases and using response times as input into the mathematical representation of the game. Answers to player demographics, response time, and representation of the game allow games to be tuned for different skilled players.

Automated Playtesting

Playtesting a common practice of *Analytical Game Design* is an integral component of user

testing, a fun and engaging game, designed to review design decisions within interactive media, such as games, to measure the esthetic experience of the game compared to the designer's intentions (Fullerton 2008). Playtesting is a lengthy process in terms of both complexity, cost, and time. Several approaches have been presented over the past few years to automate individual sections of this process (Stahlke and Mirza-Babaei 2018). These solutions aim to allow faster, more accurate iterations of design and less waste during development within a professional game development cycle.

Automated playtesting approaches have been pioneered by researchers and game studios to provide automated analytical testing of modern video games. Computer-controlled agents generate data for analysis by designers and stakeholders by playing the game at accelerated speeds and in parallel. Intelligent agents provide greater coverage of available game states, especially in open-ended game worlds, and are implemented using deep neural networks (Bedder 2019). An excellent example of automated playtesting using reinforcement learning was developed by *Prowler.io* to balance two-player games using soft Q-learning (Grau-Moya et al. 2018) that allowed automated playtests to occur in multiplayer environments.

Player Replacements & Personas

Personas have a long history within game design; separating what motivates players into categories allows the game to be assessed for different consumer groups that purchase games for different reasons; each internal driver influences how players interact with the game and can be incorporated into automated game design testing practices. Personas allow the inclusion of different motivations players have when playing games, and personas have been shown to extensively test various single-player games and allow testing in asymmetric multiplayer games with different playable characters (Holmg et al. 2018). Early examples of persona-based player replacements were powered by Monte Carlo tree search and genetic programming techniques. Modern extensions have incorporated different types of player motivation into reinforcement learning algorithms by including an additional reward signal that emulates the type of motivation for each type of player (Ariyurek et al. 2021).

Player Replacements Deep Reinforcement Learning

Work by Google highlights the strength of using machine learning to evaluate game design, and Google researchers developed a prototype game called *Chimera* (Hun Kim and Wu 2021). Google's research focusses on balancing the game by simulating millions of games using a deep reinforcement learning agent. One key issue with this research is the iterative approach and the analysis required before making changes. This tool shows the power of machine learning that allows designers to test an iteration, evaluate the gameplay metrics, and then re-test the game with appropriately designed changes, but does not help designers move the game easily and quickly to a more optimal composition. We believe that this work is a good example of how to automate testing in multiplayer games. The game is not team but features asymmetric gameplay, an example of such a project that was not achieved both at the start of this research.

Approximately, a hundred repetitions are required during the game testing phase of the development cycle to ensure that user interactions produce the expected result (TestDel 2019). A key component of this difficulty is the reliance on human observations to find bugs (Politowski et al. 2021), and excellent research by **Ubisoft** uses computer vision combined with player replacements (Paduraru et al. 2021) to detect issues without human intervention. Intelligent player replacements are able to explore the breadth and depth of the different available game states, and a trained computer vision model performs anomaly detection on the screen output that would be presented to the player. A benefit of this approach is that issues that are flagged to the developers during the testing process are immediately noticeable to the player and allow the priority of the issue; similar techniques that observe the

state of the game world may identify issues that are not noticeable to players. Issues identified using computer vision are highlighted with bounding boxes, allowing the developer tasked with investigating the issue to easily see the anomaly alongside a recording of the required input to recreate the issue, saving hours of debugging and investigation.

Assessing Content with Deep Learning

Approaches to assess generated content that can be achieved using statistical measures have received continued support; work by Lucas and Volz (2019) has shown how computer vision models can be used to generate procedural levels for *Super Mario*. The work uses adversarial neural networks to assess and generate new levels using two separate neural networks trained simultaneously.

> Which can give insight into the generative space of a content generator and its biases within that space. (Liu et al. 2020.

Generated content, such as the level's geometry, can be assessed through artificial play of the generated content. This pursuit has resulted in the generation of different reinforcement learning agents that can simulate the playtesting of PCG (Procedural Content Generation) games. This approach has been shown to evaluate Mario levels generated through an adversarial PCG pipeline (Volz et al. 2018). Automating the testing process can give PCG techniques quick insights into the quality of the generated content. Liapis et al. (2019) approach for generating levels for certain game outcomes using PCG uses AI agents to assess the quality of the generated levels. The work of Baron analyzes different PCG techniques to generate dungeons using analytical methods and allows the adaptation of different algorithms to adjust the content created for different esthetic experiences (Baron 2017).

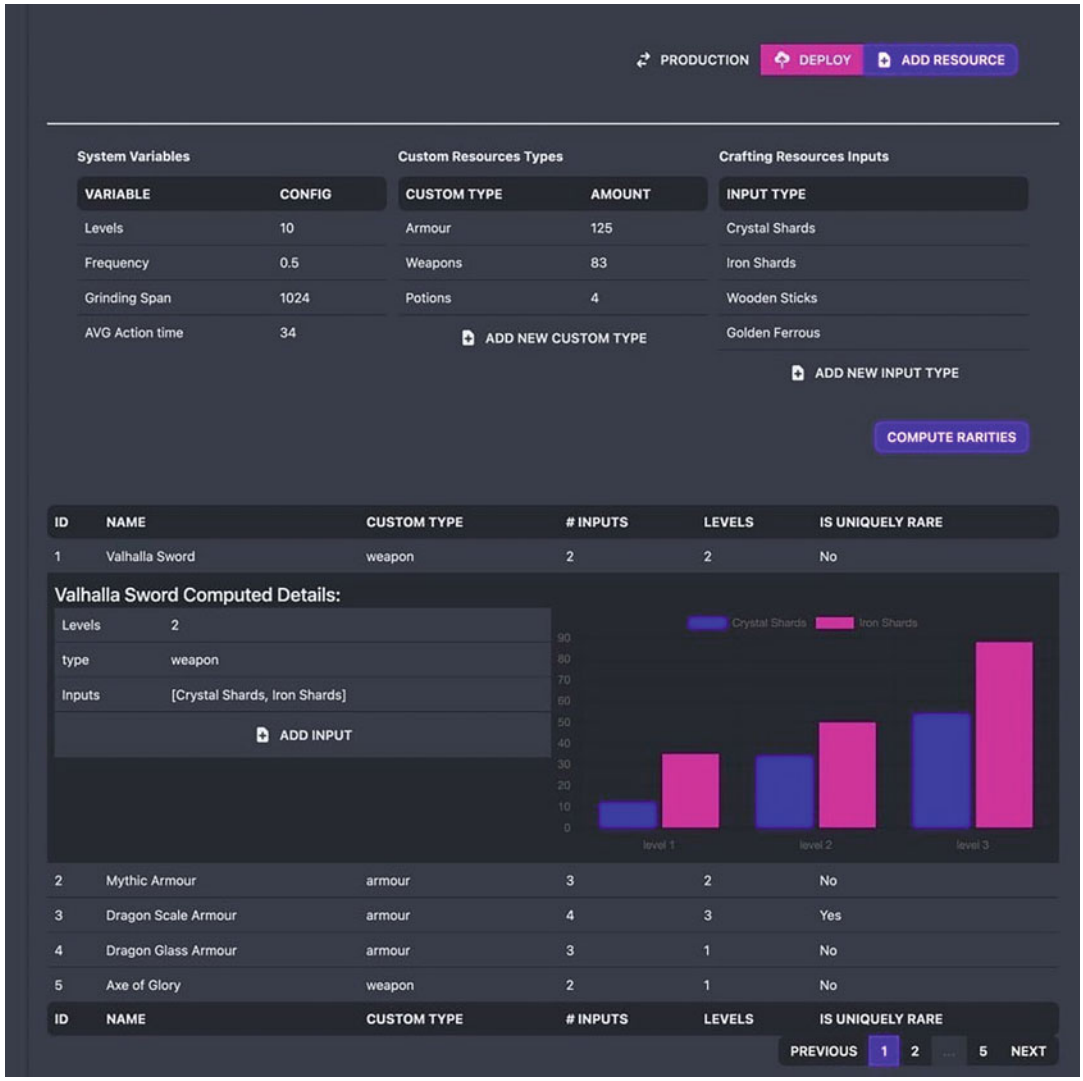
The first type of network composition explored is LSTMs, a popular type of RNN (Hochreiter and Schmidhuber 1997), which are used to generate time sequence data such as text, music, and sound. The second type of network is a generative adversarial network (GAN) that is popular for content generation due to the high levels of fidelity that can be generated from them. This is contributed due to the adversarial nature of the network architecture; GANs (Goodfellow et al. 2014) have two neural networks, one to generate the content and a second to evaluate how accurate the output is; GANs are often taught to students such as counterfeiters and police agents. As the counterfeiter improves creating forgeries, the police network becomes better at discovering fakes or outputs that are not good enough for use case within the game.

The most recent work in this area and the most relevant to this research was conducted by Liapis et al. (2019) and explored using deep learning techniques to evaluate procedural generated content. This work is spread over four key papers. This work uses deep learning to predict the outcome of games from generated data sets. The first paper titled *Using a Surrogate Model of Gameplay for Automated Level Design* refers to this neural network as a "Surrogate Model of Gameplay" (Karavolos et al. 2018), and this terminology is carried throughout the 4 papers. Liapis et al. create a data set to solve several supervised learning problems by simulating games within a first-person shooter by having agents play against each other using behavior trees. Behavior trees define each agent's policy as a branching tree that takes its state from the environment. This decision results in each agent's policy being constant throughout the data generation.

Metanomic: Game Economy Manager

With the rise of NFTs and blockchain games, managing economies have grown in importance as well as intercompatibility. "Metanomic's game economy infrastructure allows developers to build, simulate, and run balanced economies and core gameplay loops in a live, realtime environment" – Theo Priestley, CEO of Metanomic.

The dashboard and analytics tools allow finer-grained controls of the MMO world economies to understand the current supply and interactions players are having with the world's resources. An image of the dashboard can be seen in Fig. 2,



Automated Game Design Testing Using Machine Learning, Fig. 2 Metanomic Dashboard

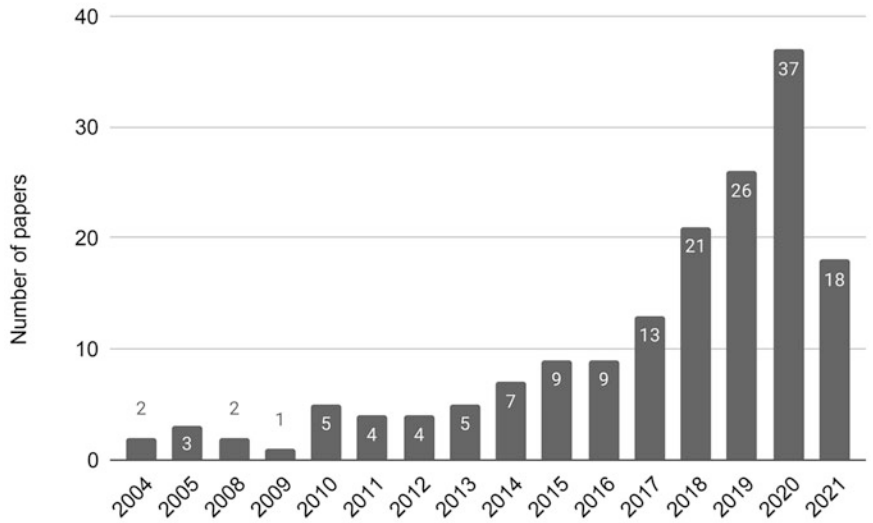
which shows the current inventory of a user and their character's history in the game. Metanomic integrates with machination diagrams and loot tables to provide a comprehensive economy manager for designers; integration with existing game engines is not currently integrated, preventing game mechanics from altering the economic systems, a key source of exploits. Metanomic has acquired *Intoolab* (announced on the 18th of May 2022), an artificial intelligence company that specializes in providing intelligent data analysis on game economies.

Toward Automated Video Game Testing

Exploratory work was carried out to explore the current sentiment toward automated game design techniques within the broader game development industry (Politowski et al. 2022). The research concluded that the desire for automated testing tools and approaches for game development was gaining traction among the survey participants; however, the difficulties of incorporating suitable techniques into existing workflows remain prohibitive toward wider adoption (Politowski et al.

Automated Game Design Testing Using Machine Learning, Table 1 Selected papers for survey, improving game testing with reinforcement learning (Politowski et al. 2022)

Author	Test Obj.	Game tested
Gudmundsson et al. (2018)	Balancing	Match 3
Roohi et al. (2020)	Balancing	Puzzle
Gordillo et al. (2021)	Exploration	3D third person
Holmgård et al. (2014)	Exploration	Doom
Zheng et al. (2019)	Exploration	MMO
Pfau et al. (2017)	Finding bugs	Adventure
Ariyurek et al. (2020)	Finding bugs	3D adventure



Automated Game Design Testing Using Machine Learning, Fig. 3 Histogram of all the 166 papers studying automated game testing over time, improving game testing with reinforcement learning (Politowski et al. 2022)

2022). Politowski et al. (2022) surveyed the sentiment of developers toward a variety of different automated testing approaches from academic research. This was achieved by summarizing the research and asking developers how *desirable, viable, and feasible* the research would be included in their workflow. The final research papers that were included in the questionnaire are included in Table 1. The included research are the filtered results of 166 papers, with 80 papers applying automated solutions to test video games. Each article was separated into semi-automatic and automatic methods; a histogram of the articles over time can be seen in Fig. 3.

This survey has clean insights into perceptions of automated testing in the game's industry despite the small sample size. The technical requirements and processes for each paper were captured in the survey questions, and participants were asked their interest in incorporating or using each technique within their workflow. Some key quotations are given from the survey responses; an example of this is shown below.

> The biggest bang for the buck would be as a build acceptance test on a CI/CD pipeline, making sure the catch obvious blocking bugs. Otherwise, it decreases significantly in usefulness. (Politowski et al. 2022.

This comment is a good assessment of the current consensus on industry sentiment. The biggest obstacle to automated testing is the technical burden that incorporating these features into the game code carries when simply managing a build server brings about significantly more benefits. Other groups have seen this issue around incorporating automated testing into game development by lightening the burden on the developers by packaging the automation as a game engine tool, which has no technical burden on the game source code. An example is *modl.ai's* glitch finder, which plays the game through Unreal Engine's input API and does not add code to the game objects; this framework-styled automation system is wonderful for brute-force tests but falls short of the requirements that would be needed when introducing reinforcement learning player replacements.

Conclusion

A variety of different aspects of game design have been explored by automated testing approaches that range from difficulty prediction (Aponte et al. 2009; Gudmundsson et al. 2018; Lee et al. 2021) that assesses how many lives it would take a player to complete new content and tailor games to different demographics or intended experiences, to higher-level game design that assesses the different options available to players and the viability of the various intended strategies that can be played (Pfau et al. 2020). Automating higher-level game design metrics provides greater value for the production team; however, it comes with greater complexity to implement and compute to assess. Testing of mechanics and systems, such as balancing intransitive relationships, is important; areas of game design that have not been explored focus on both the dynamics, such as the pacing of the game session alongside the frequency and location of key gameplay moments, which are influenced by player cooperation and strategy between different playable characters within multiplayer games. Persistent game worlds have little exploration due to the difficulty of exploring the search space by learning agents, which causes either class imbalance issues during the game balancing process or a lack of data during the assessment process.

Synonyms

Caption generation; Image captioning; Visual impairment

Definition

Visually impaired	Used in this context to refer to any significant reduction in vision that cannot be compensated for using conventional corrective lenses. Includes total blindness.
Variational Auto-Encoder (VAE)	A machine learning architecture that encodes input data into a representative, lower-dimensional feature space, then decodes it into the desired output format.
Convolutional Neural Network (CNN)	A neural network that uses an image's convolution pyramid to extract its features into a vector representation.
Recurrent Neural Network (RNN)	A neural network that is fed data in sequence and retains information from previous iterations when calculating the output of the current one.

Introduction

Image content in documents can provide important context about the topic discussed within. Though the visually impaired can't access visual content directly, the information images contain can be summarized through captioning. Captions can be conveyed through any conventional method by which the visually impaired access text; these primarily include braille readers and text-to-speech systems. Many documents come pre-captioned however, the captioning tends to be geared towards clarifying image relevance for sighted individuals rather than describing the contents themselves. To remedy this, automated captioning systems have been and are being developed to give the visually impaired some access to this type of content.

Designs of Image Captioning Systems

Most modern image captioning systems rely on a VAE architecture. Many alternatives existed before the popularization of neural networks (Kulkarni et al. 2011) but they have since been either replaced by or enhanced with VAEs.

The first neural image captioning system (Karpathy and Fei-Fei 2015) used a CNN to encode image features and an RNN to generate text captions word by word. While the basic

architecture remains the same, many tweaks to this system have been developed since. A common extension is to include an attention mechanism (Xu et al. 2015) or even replace the RNN and/or the CNN with a Transformer (Liu et al. 2021).

Encoding is the step that has undergone the most drastic changes. These changes primarily take the form of various pre-processing steps. Neural Baby Talk (Lu et al. 2018) first applies an object detection algorithm to the source image before feeding it into the CNN.

Adaptation for the Visually Impaired

While automated image captioning may not have been designed with the visually impaired in mind, its connection is obvious. Several applications have been specifically designed to aid the visually impaired in navigating visual media online and in the real world. These rely on two types of methods which are not mutually exclusive.

Data-Oriented Methods

A key factor for the successful adoption of these models is training on image captioning datasets with labels better suited towards aiding the visually impaired. These captions should contain not just a basic scene description but also include detailed information about the scene and its actors.

One model (Elamri and de Planque 2016) uses a very similar architecture to the basic one described here, with a CNN leading into an LSTM but is trained on the Microsoft COCO Caption dataset (Chen et al. 2015) which uses strong descriptive language in its labels.

Another (Ahsan et al. 2021) uses the Vizwiz dataset which contains images labeled in concert with visually impaired individuals. This training data includes all-important image features that would assist the visually impaired in understanding a scene.

Model-Centric Methods

Better data is insufficient for solving this problem. Models also need to be extended to include more detailed information about individual actors. They also need to be able to handle more complex interactions between them.

The addition of object detection before convolution as in Neural Baby Talk (Lu et al. 2018) allows for more detailed information about individual actors in the scene. This preprocessing step significantly increases performance on more sophisticated image captioning datasets.

Another implementation (Makav and Kılıç 2019) uses a significantly more complicated architecture for the image convolution phase. The architecture in question is VGG16 (Simonyan and Zisserman 2014) which combines image convolution layers with fully connected deep learning layers to allow for higher-level feature extraction.

Combining Approaches

Many applications geared towards the visually impaired lean heavily on a data-centric approach to improvement. While this is an important step, the models being used are not sophisticated enough to capture the high-level language used in the training data. As a result, these projects perform only as well as the associated model would on a normal dataset.

Occasionally performance is even reduced in comparison to those on standardized datasets because the model develops a tendency for memorization due to its inability to learn the complexities present. A common outcome of this is object hallucination (Rohrbach et al. 2018) where objects that often appear together in the same image both appear in the caption, even when one is not in the image being captioned.

Limitations of Current Systems

Image captioning systems used today have a few important limitations that need to be addressed. The most prominent of these is that captions are generally simple and cannot explain interactions in detail. This issue is in large part a matter of limited compute resources and model complexity.

The solution of applying an object detection algorithm before convolution remedies this

somewhat but in turn limits the amount of information carried about the scene as a whole. This type of general information would be important to convey to a visually impaired individual.

Another issue arises in situations where there is text contained within images. While text extraction from images is very nearly a solved problem, no existing solutions take that data into account when generating captions. Without information about the text contained in the scene, the vast majority of an image's meaning could be lost.

These are the primary issues with modern image captioning systems designed for the visually impaired.

Next Steps

Addressing these limitations is by no means a simple task. As one tries to train a model to learn more complex representations, the required model complexity and size goes up drastically. To achieve real progress in these areas it may be necessary to focus on improving model efficiency and downscaling before moving to bigger challenges. In the meantime, it does not hurt to consider potential methods for resolving these issues.

Holistic Scene Understanding

Concerning complete scene understanding outside of object interaction, increasing the CNNs depth, with a VGGNet-based model, for example, may improve overall scene comprehension.

Employing a visual self-attention mechanism within the CNN could provide similar results by emphasizing important connections between image regions (Xu et al. 2015). Taking this a step further and replacing the CNN entirely with a Transformer has been explored as well (Liu et al. 2021).

In-image Text Data

As far as including text recognition in image captioning systems, the obvious solution would be to simply run text detection first and incorporate an embedded vector representation into the feature vector from the image processing network. Unfortunately, this would likely result in the text itself being lost in the process.

An alternative solution would be to use object detection and then explicitly connect the observed text to its corresponding bounding box. This would certainly better capture the contents of the text but may result in poorly phrased captions in unusual circumstances.

Document-Aware Captions

While images often exist independently online, the visually impaired will rarely interact with them. In general, most images would be encountered within another document or web page.

Leveraging this fact could allow the detection of named entities within the text and connecting them to objects detected within the image. This could allow the caption to contain relevant contextual information such as the actual name of a given person or object rather than just the type of object. The corresponding text data could also be used as a basis for generating captions, using a similar methodology to question answering systems trained on large documents.

Conclusion and Discussion

In conclusion, automated image captioning is a complex and interesting field at the intersection of natural language processing and computer vision. The visually impaired would benefit from some access to the information contained within images and captioning is a good starting point to achieve this.

While some work has already been done, there is plenty of room for improvement. Current systems don't capture enough information to be much more useful than baseline models. This is unfortunate, but it means that, as the baseline models improve, so too will their applicability to the situation of the visually impaired.

Bayonetta 2, an Analysis

Isaac Wake[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Hack-and-Slash

Definitions

Action – a genre of games defined by quick gameplay and fighting several enemies in real time.

Hack-and-Slash – a subgenre of action games that challenges the player to fight hordes of enemies that seem weak individually compared to the powerful player character. They typically ask a player to complete a level filled with minor enemies with a more powerful enemy at the end.

Basic Information

- Game Title: Bayonetta 2
- Developer/Publisher: PlatinumGames/Nintendo
- Series: Bayonetta
- Game Engine: Criware
- Platforms: Wii U, Switch
- Release Date: October 24, 2014 on Wii U, February 16, 2014 on the Switch
- Genre(s): Action, Hack "n" slash
- Mode(s): Single player, multiplayer
- ESRB Rating: M

Game Overview and Target Audience

Bayonetta 2 is an action and hack-and-slash game. The target audience for this game are the people who are looking for a fast-paced, thrilling action game.

© Springer Nature Switzerland AG 2024
N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

Gameplay and Mechanics

The gameplay of Bayonetta is a hack-and-slash game that keeps gameplay fresh with a variety of unlockable weapons that can be equipped to Bayonetta's hands and legs giving the player a variety of customization while also changing the way Bayonetta controls and/or interacts with the environment. For example, Bayonetta can equip weapons resembling a chainsaw to her feet and katanas to her legs allowing her to kick with sword attacks and swing with chainsaw attacks, but if a player equips the katanas to her hands she has a larger variety of attack and equipping the chainsaws to her feet allows her to skate with chainsaws on her feet, making her faster and doing chip damage as she whirrs by enemies while also being able to still do kick attacks. Holding the slide button while attacking slices through enemies like a chainsaw would do to a tree.

One of the biggest features of the Bayonetta series is Witch Time. Witch Time is activated when Bayonetta perfectly dodges an attack. It gives the player the upper hand by slowing down time for a couple seconds, allowing for a flurry of attacks to be performed while the enemies are slowed. Witch Time earns Bayonetta more climax toward the Climax Gauge.

When the Climax Gauge is filled, Bayonetta can activate this gauge for an assortment of options. The most destructive option is the Umbran Climax. This allows Bayonetta to perform insanely powerful and flashy attacks, like literally smashing enemies across levels. The gauge can also be used to charge certain weapons and torture attacks.

World, Story, and Characters

Bayonetta 2 takes place on the mountain of Fimbulventr and the depths of Hell. While traveling through and between these realms, the player will encounter enemies from Heaven and Hell.

Bayonetta 2 revolves around a female witch, named Bayonetta, and her journey to save her friend Jeanne's soul from the literal depths of Hell. Bayonetta travels up the mountain of Fimbulventr with an unexpected partner named Loki, a boy who deals with his forgotten past and powers he did not know he could wield. A weapon supplier and infernal bar owner named Rodin helps Bayonetta by creating weapons from the souls of the dead. Bayonetta's somewhat love interest, called Luka, follows Bayonetta trying to solve several mysteries surrounding the events of Loki, Heaven, and Hell. There are only two real antagonists, Loptr and the Masked Lumen, both of which are shrouded in mystery.

Levels

Most of the levels in this game take place in the destroyed town of Noatun, temples, and the depths of Hell.

Interface

The game contains a very solid interface which contains everything a player needs to know while defeating angels and demons. This is Bayonetta's health bar and her climax meter.

On the right side of the screen, the amount of halos/money the player has and their combo points counter is shown.

The bottom right is home to a health bar for larger enemies or bosses.

Public Reception

The public reception of Bayonetta 2 on Switch was received well with 9/10's all down the board from a majority of most major gaming sites. GameSpot reviewer Mark Walton said the game "will be remembered as an absolute classic" and awarded it a perfect 10/10, the seventh game on the site to get a perfect score. This game is praised for being a sequel that feels exactly like the original while also fixing and improving upon the game's formula.

Controversies

Most of the gripes from this game come from it being a Nintendo console exclusive, originally releasing on the Wii U. Although this is true, Nintendo helped revive the franchise as Sega (the previous publisher of Bayonetta 1) wanted to pursue other interests. Although the Wii U version did not sell well due to the console not selling that well, the Nintendo Switch has sold considerably better and the rerelease of Bayonetta 1 and 2, with a third game being teased, has appeased some who had availability complaints.

There is also a strong controversy around the visual representation of Bayonetta as a character in the game. Anita Sarkeesian uses Bayonetta as an example in her "Lingerie is not armor" video on YouTube. However, some other people opine that Bayonetta is a feminist icon.

Similar Games

God of War and Devil May Cry are very similar games (Bayonetta Director Hideki Kamiya worked on the Devil May Cry games), but what

sets Bayonetta apart from these games are the customization options, game mechanics, and the protagonist being a female.

Definition

In an interactive artistic context, biosensing studies the detection, measurement, variation, and translation of electrical potentials in the human nervous and motor system as a strategy for controlling parameters in the virtual domain of a digital interactive system.

Introduction

The unprecedented technological advances in terms of computational power, software integration, and miniaturized sensor technologies have fostered new artistic content creation methods in the domains of interactive music, art installations, and digital game design, to name but a few. In this context, biosensing is becoming a pervasive modality of control in interactive systems. In other words, artistic-related practices have been adopting psychophysiological electrical potentials of human subjects, i.e., biosignals, as a strategy to control the creation of interactive content towards adaptive, symbiotic, and immersive experiences.

In this entry, the authors present a user-centered taxonomy of biosensing technology, which aims to guide interactive artists in selecting appropriate biosensors for a particular interactive application design. Particular emphasis is given to the mappings between biosignals' level of control and temporal response and the nature of the system output. In pursuing such a user-centered perspective over biosensing technology, the authors seek to extend existing taxonomies beyond the technical specifications of the sensors, thus, promoting a fluid use of such technology by interactive artists.

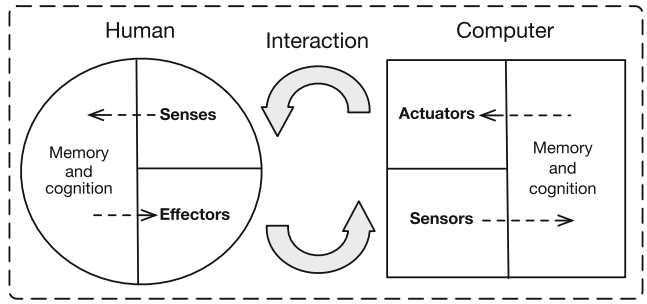
The remainder of this entry is organized as follows. Section "Human–Computer Interaction in Interactive Art" defines concepts such as interactive art, human–computer interaction. Then, in section "Interaction Modalities," is presented artistic-related interaction modalities including biosensing. In section "Towards an User-Centered Taxonomy of Biosensing," the authors review a range of taxonomic perspectives of biosensing technology proposed in related literature and further detail their user-centered taxonomy. Examples of interactive application scenarios of a user-centered taxonomy are presented in section "Application Scenarios of a User-Centered Taxonomy," which discussed typical mappings between biosensor technology and interactive content creation using the proposed taxonomy. Finally, on section "Conclusions," the authors outline the conclusions of their study.

Human–Computer Interaction in Interactive Art

Digital art is increasingly interactive. Some of it is built on interactions that evolved from computer games and device usage. Much of the interaction is intended to engage the audience in some form of interactive experience that is a key element in the aesthetics of the art. The interactive artist is often concerned with how the artwork behaves, how the audience interacts with it and, ultimately, in participant experience and degree of engagement with the art object.

In interactive art, the art object has an internal mechanism that enables it to change or be modified by an environmental factor, or human, which has an active role in influencing the degree of changes (Edmonds et al. 2004). In today's interactive art, where the artist and the audience play integral participant roles, the computer's role has immense potential in defining the degree of interaction, and also managing the real-time result of that interaction. Issues relating to human–computer interaction could be considered as important to interactive art creation as colors are to painting (Candy and Ferguson 2016).

Figure 1 shows the information flow of a human–computer interaction Bongers (2000) as a two-way control and feedback process. When interacting with a computer, humans take action in response to a sensed environment. In turn, computers capture the transformed environment and act accordingly using transducers – *sensor* devices that translate real-world signals into machine-world signals – and *actuators* that translate machine-world signals into real-world signals that can be perceived by humans.



Biosensing in Interactive Art: A User-Centered Taxonomy, Fig. 1 Redraw of Bongers (2000) interaction scheme, which includes two agents: a human and a computer. A feedback loop is created between both agents, which sense the external world using natural and artificial sensors. Both human effectors and computers actuators disturb the environment and act upon it

An example of this interaction loop can be demonstrated with a simple user-control case. When a user presses a computer keyboard key, the system (i) senses the mechanical force applied onto the key, and assigns that action to a specific programmed instruction – a real-world signal is translated into machine-world signal – and, in turn, the system (ii) maps that instruction to a specific symbol and translates a machine-world signal into real-world signal. The result being the visual feedback of the assigned character on the computer screen which can guide the user for future actions.

Thus, to foster human–computer interaction, a system should be equipped with (i) the ability to *sense* the external environment, i.e., a system capable of converting some kind of physical energy, e.g., kinetic or biosignal into electricity and then to codify that input into digital data in order for it to be recorded, analyzed, and manipulated and (ii) the ability to *actuate* on the external environment, i.e., being capable of converting digital data into some form of energy that can be perceived by a human being, e.g., visual/sound or mechanic cues. Sensing and actuating are specifications that allow a system to be controlled, report its current state, and guide the user towards the next possible actions.

In Bongers (2000), both the human and machine's memory and cognition are essential components in building the interaction loop. In an interactive system, ideally the "conversation" between the human and the system should be mutually influenced by the intervention of both humans' and machines' memory and cognition permitting the interaction with information, the changing of the environment, and thereby altering the subsequent information that is received back by the system.

Interaction Modalities

In Bongers (2002), human–computer interaction makes use of what the author refers as interaction modalities – as communication channels between a human and a system – and those interaction modalities involve (i) input modalities which imply senses such as seeing, hearing, smelling, tasting, and touching which are used to explore the surrounding environment and (ii) output modalities, mainly involving the motor system, e.g., handwriting, speaking, or moving things around, that are used use to act on the environment.

Biosensing, as a measurement of the human psychophysiological activity and its use as a strategy for controlling parameters in the domain of a digital interactive system, is an interaction modality of special interest for the present study.

In detail, human psychophysiological activity relates to brain, skeleton, and cardiac muscles, but also skin functions, which all generate electrical potentials. These signals can be measured by electrodes and used to control a digital interactive system. Biosensing captures biosignals (Arslan

et al. 2005; Ortiz-Perez et al. 2011; Ortiz et al. 2015) by detecting, measuring, and translating the electrical potentials in the human nervous and motor system functions, e.g., electromyographic signals, measured on the skin which are related to muscle activity, and electroencephalographic signals, measured on the scalp which is related to brain activity. Recent sensor technology has been developed to detect and measure these functions, notably to support medical care (Stern et al. 2001; Cacioppo et al. 2007; Webster and Eren 2017).

Beyond medical applications, biosensor technology has been attracting the attention of interactive artists who have been increasingly adopting this technology to control parameters of interactive digital systems.

Towards an User-Centered Taxonomy of Biosensing

Existing Taxonomic Perspectives

A wide range of taxonomic perspectives of biosensing technology, rooted in different disciplines and applications, have been proposed in related literature. In Horowitz and Hill (1989), sensor technologies are organized technically according to their electronic circuit design and in (Sinclair 2000) according to the kind of physical energy measured by a sensor, i.e., mechanical, gravitational, electrical, thermal, or magnetic. In Bongers (2000), and referring to the design of interactive musical systems, sensor technologies are categorized based on the ways humans can change the state of the surrounding environment pointing output modalities mainly related to muscle actions, which result in mechanical movement, air flow, or sound production.

In game research, Kivikangas et al. (2011) review the biosense method by presenting a taxonomically review of the application scenarios of biosignal as a way to assess game experience arising from emotional reactions, mainly related to valence and arousal dimensions, and in Leite et al. (2000), Kleinsmith et al. (2003), and Bernhaupt et al. (2007), a taxonomy is presented that takes into account factors such as affective responses by the player to game playing.

Taking into account the use of biofeedback to control game mechanics in Nacke et al. (2011), Pedersen et al. (2010), and Figueiredo and Paiva (2010) Nogueira et al. 2016) formalize biofeedback game mechanics with respect to players' emotional states – modeling player experience for driving interactive content creation.

Table 1 lists biosensor technology commonly adopted in interactive art domain and details the nature of the psychophysiological electrical

Biosensing in Interactive Art: A User-Centered Taxonomy, Table 1 Commonly used sensor technologies in the field of interactive arts and their respective measurable phenomena expressed in hertz (Hz)

Sensor technology	Abbreviations	Measurable phenomena	Frequency (Hz)
Gaze interaction	GAZE	Position, movement, and pupil dilation of gaze with a sensor located on the screen	30
Electromyography	EMG	Activation of facial or body muscle tissues	20–2000
Respiration	RESP	Chest the breathing rate and volume	Measured in extension capacity
Temperature	TEMP	Thermal feedback	Up to 5000
Electrocardiogram	ECG	Electrical activity of the heart	0.05–100
Heart rate variability	HRV	Time difference between two sequential heartbeats	HF (0.15–0.40) LF (0.04–0.15)
Electrooculgram	EOG	Eye motion analysis with a body-worn sensor	DC to 10
Electrodermal activity	EDA	Tonic level of electrical conductivity of skin	0–2.8
Electroencephalogram	EEG	Electrical changes on the scalp	0.05–100

Sensors such as ECG, EEG, EMG, TEMP, and EOG measures in Aller et al. (2000), EDA (da Silva et al. 2014), and HRV (Bakhtiyari et al. 2017). GAZE and RESP sensors have different responses; the latter is measured in extension capacity range, e.g., ranging from 35% to 65%, and the former's accuracy depends on the angular average distance from the actual gaze point

potentials it measures. The sensors were selected based on their common application in interactive arts, availability, low cost, miniaturization, and quick integration with software applications.

A User-Centered Taxonomy of Biosensing

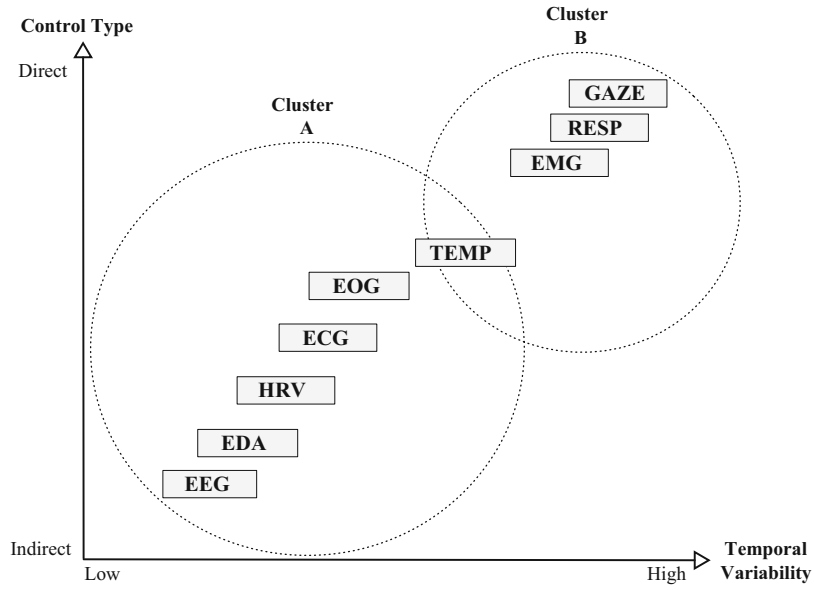
The authors propose a user-centered taxonomy of biosensor technology to assess the broader picture on the use of biosensing technologies as a strategy for controlling parameters in the virtual domain of a digital interactive system. In pursuing such a user-centered perspective over biosensing technology, the aim is to extend existing taxonomies beyond the technical specifications of the sensors, thus, promoting a fluid use of such technology, and its intuitive use, by interactive artists.

In greater detail, the proposed user-centered taxonomy guides the process of selecting the most suitable sensor technology for a specific task based on two dimensions: (i) the degree of control over psycho-physiological human functions, i.e., the ability the subject has to manipulate her own psychophysiological activity and consequently alter the sensor response and (ii) the temporal variability, i.e., the rate of temporal noticeable change in the captured electrical potentials. For example, the author's taxonomy provides an answer to the artist, which aims to use biosignals to control the (long-term) digital game mechanics such as daytime or the weather conditions by pointing to a low temporal variability response sensor with an indirect type of control.

Figure 2 shows the user-centered taxonomy of biosensing technology for interactive art contexts. It includes the biosensors technology listed in Table 1. The two dimensions of the taxonomy, i.e., the temporal variability of the psychophysiological function and the type of control over particular function, are assigned to the horizontal and vertical axes, respectively.

The temporal variability in the horizontal axis reports the degree of temporal variability from low to high. For example, a GAZE sensor has high variability as it measures eye movement, which can naturally be very fast. On the other side of the spectrum, the EEG sensor has a much lower variability as it measures brainwaves can have a slower rate of change. The temporal variability is related to the measurable phenomena expressed in hertz presented in Table 1.

The degree of control over the psychophysiological functions by subjects is denoted in the vertical axis and is expressed in a scale from direct to indirect control. In greater detail, the scale reports the degree of control humans have over their psychopsychological functions and the ability to deliberately alter the response of the captured data. For example, humans have a



Biosensing in Interactive Art: A User-Centered Taxonomy,
Fig. 2 Physiological measures according to a distribution on two axis: on the horizontal axis, the temporal variability response stimuli/sensor, and on the vertical axis, the level of direct control of the electrical potentials generated. The authors denote two clusters, A and B, grouped according to sensor's type of control and response. The measurable phenomena captured by the different sensors is explained in Table 1

direct-explicit control over a muscle impulse, captured by an EMG and a more indirect-implicit control over skin conductivity using an EDA.

In Fig. 2, a diagonal disposition of the biosensors can be identified, showing that the horizontal and vertical axes are intertwined in such a way that the faster the responses obtained from the sensors, the more direct control users have over their measures and evolution. Moreover, from this tendency the authors highlight two overlapping clusters. This overlap is due to the fact that there are sensor technologies which have slow changing responses that can be altered by a sudden change in the environment that they are measuring. An example of this overlap is the TEMP sensor which typically has slow response but the user can induce a more immediate response by blowing air into it.

One remaining dimension is of consideration here: body intrusion. Despite its relevancy in the choice of biosensors for a particular task, the authors believe that the miniaturization of sensor-technology will eventually make it ubiquitous and pervasive in all artistic applications scenarios. Even so, interactive artists must be aware of the pertinence of this dimension when building interactive content.

Application Scenarios of a User-Centered Taxonomy

Based on the two identified clusters in Fig. 2, the authors now discuss typical mappings between biosensor technology and interactive content in two main domains: game design and game audio. The authors believe these same principles can be applied to other forms of interactive biosensing driven art contexts, such as interactive music or performance art.

In game design, biosensors from cluster **A** are typically applied to control implicit, slow-adapting, or background aspects of a game, such as level generation conditions. For example, the slow-changing HRV function can be mapped to evolve long-term game settings such as the weather conditions or to control artificial intelligence aspects of game that are not so noticeable. On the other hand, the slow pace of an EEG measure can be used to define artificial intelligence parameters of nonplayer characters' level of reaction to the player presence. For creating interactive game audio, the sensors from cluster **A** allow the control of higher level musical features such as tempo, i.e., a faster or slower tempo in music expressed in bpm (beats per minute), or the soundtrack general mood, i.e., a more tense or relaxed type of music can be mapped to an HRV sensor.

Biosensors from cluster **B** are better adapted to control explicit interactions or foreground actions. For example, an EMG sensor, which measures fast-changing facial or body muscle tissues, is well-adapted to control player rapid actions, e.g., define the impulse of a character's jump. The fast response and highly controllable RESP sensor can be used to define the number of enemies when the player is trying to accomplish an undercover mission. For interactive game audio cluster **B** is better adapted to control low-level sound features such as the audio level of determined sound effect, e.g., a GAZE sensor can be used to raise the audio level of an observed game object to focus the player's attention or to define the location of a sound event in the scope of the stereo image.

Conclusions

The authors presented a user-centered taxonomy of biosense for interactive arts which aim is to provide artists with a framework to assess the broader picture on its use as a strategy for controlling parameters in a digital interactive system. In pursuing such a user-centered perspective over biosensing technology, the authors sought to extend existing taxonomies beyond the technical specifications of the sensors in order to assess a broader picture of biosensing technologies, thus, promoting a fluid and intuitive use of such technology by interactive artists. By providing use cases examples which discussed typical mappings between biosensor technology and interactive content creation in domains such as game design and game audio, the authors intended to validate their user-centered taxonomy of biosense in interactive art.

Bounding box hierarchy; Bounding sphere hierarchy

Definition

A bounding volume is a geometric primitive that encloses one or more objects and leads to cheaper overlapping tests (Ericson 2005). The bounding volumes most frequently used are spheres, boxes, and ellipsoids. The bounding volume hierarchy is a tree structure used to represent the set of geometric objects, which are enclose in bounding volumes. A rigid body is a solid body without deformation or whose deformation is so insignificant that it can be neglected.

Introduction

Bounding volumes and binary space partitioning belong to the acceleration structures used to increase the speed for applications that require to determine intersection between two or more objects. Bounding volume is a technique for object partitioning, which is based on object subdivision and objects level of details, whereas binary space partitioning is a technique for space partitioning, which is based on the space subdivision and space level of details (Luque et al. 2005; Weller 2013). Techniques based on hierarchical bounding volumes are commonly used for collision detection. An object is a triangular mesh, which is bounded by a hierarchy of bounding volumes for collision detection. It is divided hierarchically, usually by a recursive method, and then a bounding volume hierarchy (BVH) is used to represent each part of the object in such a way that the complete object is represented in each level of the BVH. A BVH is a tree structure in which the problem of detecting a collision between two or more objects can be reduced to detect collisions between their BVHs representation. On the one hand, if bounding volumes of two nodes do not overlap, there is no collision for the parts bounded by these bounding volumes. On the other hand, if bounding volumes of two leaf nodes overlap, the corresponding triangles must be tested for intersection. In the next section, it is presented a brief explanation of spheres, axis-aligned bounding boxes (AABB), and oriented bounding boxes (OBB).

Spheres

It encloses an object with the minimal sphere; it is usually called the bounding circumference in a two-dimensional space and bounding sphere in a three-dimensional space (Arcila 2011; Weller 2013; Dinas and Bañón 2015). One advantage of sphere as bounding volumes is its efficiency to calculate the intersections and distance between a pair of sphere. Although spheres are invariant to translation and rotations, they are not good bounding volume for elongated objects. To calculate the bounding sphere, it is found the largest distance between a pair of vertices of the polygon (in two dimensions, see Fig. 1) or polyhedron (in three dimensions).

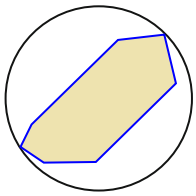
The intersection between spheres is straightforward; it is just enough to calculate the distance between their centers and the sum of their radius, and to compare these quantities. For instance, the pair of spheres depicted in Eqs. 1 and 2 have centers $(x1, y1, z1)$ and $(x2, y2, z2)$ and radius $r1$ and $r2$, respectively.

$$(x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2 = {r_1}^2 \quad (1)$$

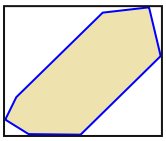
$$(x - x_2)^2 + (y - y_2)^2 + (z - z_2)^2 = {r_2}^2 \quad (2)$$

There is not intersection between the circumferences if the condition 3 holds; otherwise they intersect.

Bounding Volume Hierarchies for Rigid Bodies, Fig. 1 Bounding circumference



Bounding Volume Hierarchies for Rigid Bodies, Fig. 2 AABR



$$\sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2} > r_1 + r_2 \quad (3)$$

Axis-Aligned Bounding Box (AABB)

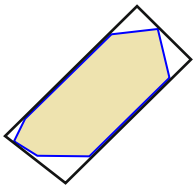
An AABB is a minimal enclosing box that contains the object; it is usually called the axis-aligned bounding rectangle (AABR) in a two-dimensional space and axis-aligned bounding box in a three-dimensional space (Zhigang et al. 2010; Arcila 2011; Weller 2013). The main benefits are that it is simple to find the box, the box is invariant to translations, and the test between a pair of boxes is straightforward; nevertheless, this volume is not invariant to rotation, as a result, changes in the objects direction require updates in the bounding boxes (Fig. 2).

The procedure of testing whether two boxes overlap is simple. Check if one box lies completely on the half-space (not containing the object) of one face of another box, then the two boxes do not overlap. That is, if there exists a separating plane so that two boxes lay on different half-spaces of the plane, they do not overlap.

Orientation Bounding Box (OBB)

It is the minimal box that encloses the object and takes into account the object orientation; it is usually called the oriented bounding rectangle (OBR) and oriented bounding box in a two-dimensional and in a three-dimensional space, respectively (Zhigang et al. 2010; Arcila 2011; Weller 2013). The most significant advantage of this volume is the invariance to translation and rotations; however, the collision test for OBBs (or OBRs) is computationally more expensive than the AABBs (or AABRs) test (Fig. 3).

Bounding Volume Hierarchies for Rigid Bodies, Fig. 3 OBR



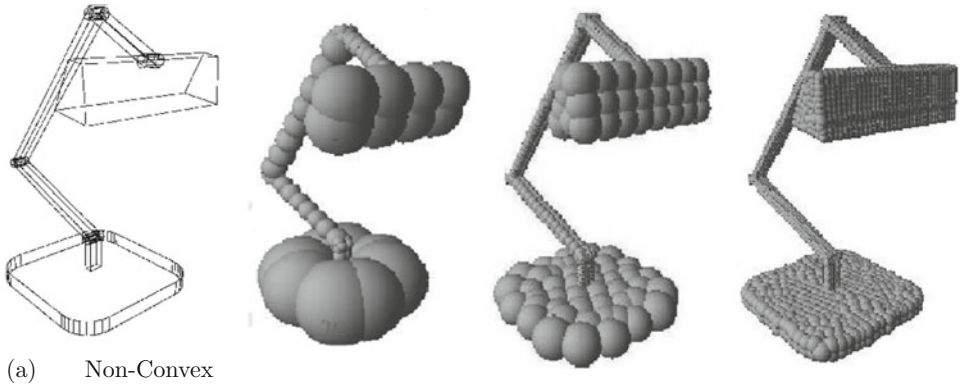
The same procedure used to determine if two boxes overlap can be used to determine the intersection between OBBs.

An Example of Bounding Volumes Hierarchies for Spheres

Figure 4 depicts an example of bounding volumes of a lamp using spheres. Figure 4a shows a nonconvex polyhedron with lamp shape, and it was decomposed into a set of ten parts, which are convex polyhedra. The lamp is compounded by one (1) base, one (1) lamp shade, four (4) pipes or tubes, and four (4) junctions or connectors. In Fig. 4b, there are depicted the three levels of the hierarchy, which has $2^3 = 8$ bounding volumes in each part (80 spheres in total). Figure 4c, d depict the levels 6 and 12 of the hierarchy, respectively; the level 6 has $2^6 = 64$ bounding volumes in each part (640 spheres in total) and the level 12 has $2^{12} = 4.096$ bounding volumes per part (40.960 spheres in total).

Some Bounding Volumes

Following, a short list of common bounding volumes.



Bounding Volume Hierarchies for Rigid Bodies, Fig. 4 Representation of an object Lamp by spheres. (Dinas et al. 2009)

- *Ellipsoid*: Ellipsoids are tighter fitting than spheres for elongated objects (Rubino et al. 2015).
- *Cylinder*: It uses the radius of bounding circumference of the shape and a swept line (Chan and Tan 2004).
- *K-Discrete Orientation Polytopes (K-DOPs) or Fixed-Direction Hull (FDH)*: A DOP is a generalized AABB. It is constructed by taking a number k of appropriately oriented planes at infinity and bringing them closer to the object until they collide (Weller 2013; Dinas and Bañón 2015).
- *Oriented Discrete Orientation Polytopes (Or-DOPs)*: An Or-DOP is similar to a K-DOP, but it is a generalization of an OBB rather than an AABB (Suaib et al. 2013).
- *Swept Sphere Volume*: The representation is straightforward: a radius and a swept volume. The most important swept volumes are point swept spheres (PSS), line swept spheres (LSS), and rectangle swept spheres (RSS). The advantages of these volumes correspond to the sphere advantages (Tang et al. 2014).
- *Cloud of Points and Convex Hull (CPCH)*: It constructs a convex hull for a cloud of points; it is the smallest convex volume containing the object and, hence, a hull is a tight bounding volume (Figueiredo et al. 2010). Research on clouds of points includes mostly surface reconstruction; they are important for animated three-dimensional graphics.

The combination of two or more BVHs was proposed by (Arcila 2011) as a double BVH. The outer (minimal) bounding volume has been widely used; it determines the collision and accelerates the process in broad-phase, whereas the inner (maximal) bounding volume accelerates the collision acceptance process. Additionally, a combination of AABB and ellipsoids for three-dimensional for a sequence of images was recently proposed by Rubino et al. (2015), they worked on objects reconstruction from a sequence of images in open and close scenarios.

Bounding Volumes Requirements

Several literature about the bounding volumes includes the importance, minimal requirements, construction cost, test cost, evaluation tests, techniques, applications, among others (Zhigang et al. 2010). Because of their importance, several authors have reported their impact and cost of computing, and have implemented strategies to decrease the cost (Yoon and Manocha 2006), whereas other authors have reported works on requirements for optimal bounding volumes (Weller 2013):

- *Tight fitting to approximated objects*: Tighter fitting bounding volumes are computationally expensive; it is hard to calculate a unique bounding volume that adjusts different objects. Hierarchies are one solution to approximate the object (Bradshaw 2002).
- *Efficient creation*: The complexity of the bounding volume is mainly the complexity of its creation; however, more complex volumes should be tighter fitting (Lauterbach et al. 2009).
- *Efficient updating*: If a bounding volume is invariant to rotation and translation, it does not require to be updated; however, not always they are invariant to both geometrical transformations (Spillmann et al. 2007).
- *Efficient overlap tests*: Low computational costs are associated with simpler bounding volumes (as spheres and boxes); however, they are not as tighter fitting as others (Zhigang et al. 2010).
- *Low memory usage*: The simpler bounding volumes use lower memory and have low computational cost; nevertheless, they are not as tighter fitting as others (Yoon and Manocha 2006; Weller 2013).
- *Suitable for hierarchy construction*: A bounding volume tree helps to decrease the number of overlapping tests, and they can be used to approximate the objects shape (Spillmann et al. 2007).

All requirements are essential; however, there is not a bounding volume that fulfills them completely; the selection depends on the application. Nevertheless, efficiency in bounding volumes is equally important to the following requirements of the hierarchy (Bradshaw 2002):

- *Volume Approximation*: Children nodes represent tighter fit of the object than its parent.
- *Covered Area*: Children nodes must cover the same parts of the object covered by their parent.
- *Automatic Creation*: Hierarchy construction does not use human interaction.
- *High Degree of Accuracy*: Bounding volumes should fit the original model as tightly as possible.

Bounding Volumes Performance

Performance of Bounding Volumes can be evaluated using Eq. 4 (Bradshaw 2002; Weller 2013; Dinas and Bañón 2015).

$$T = N_u C_u + N_v C_v, \tag{4}$$

where T is the total cost function for detecting interference between a pair of objects represented by a bounding volume. N_u is the number of bounding volumes updates during the traversal of the hierarchies, and C_u is the average cost of updating a bounding volume due to the motion. N_v is the number of overlapping tests performed over the bounding volumes, and C_v is the average cost of performing an overlapping test between a pair of bounding volumes.

However, Eq. 4 was extended to Eq. 5 in order to separate bounding volumes and primitives (Weller 2013).

$$T = N_u C_u + N_v C_v + N_p C_p, \tag{5}$$

where N_p is the number of overlapping tests performed over primitives, and C_p is the average cost of performing an overlapping test between primitives. (Suaib et al. 2013) included C_o in Eq. 6. C_o is used to include any additional time caused by transformation updates or coordinates updates for the objects. Similarly, Ericson (2005) define C_o as a one-time processing.

$$T = N_u C_u + N_v C_v + N_p C_p + C_o \tag{6}$$

For instance, due to spheres and OBBs are invariant to rotation, they eliminate the values N_u and C_u from Eqs. 4 and 5 but the value N_v increases. In contrast, the reduction of overlapping test over the bounding volumes (N_v) increases the number of overlapping test over primitives (N_p).

Biometric authentication; Brain-computer interface; EEG signal

Definitions

Human biometric techniques are presented as another type of security authentication to cover

the problems of password authentication. Brainwave is another human biometric, which recently is one of the popular subjects for scientists and researchers. Brain-computer interface (BCI) is a method of communication based on neural activity's communication created by the brain.

Introduction

In the past, people used to have a suitcase to keep their important documents like keys, money, bank account booklets, letters, photos, etc. which they could lock the suitcase to keep them secure. Today, people can keep all of that information in their personal computers, mobile devices, social networks, and the cloud storages, which in this case, information security and data protection play a crucial role in them. Security and accurate authentication methods have become a top priority within information security, which is necessary as it allows companies and people to keep their systems and devices protected by authorizing only authenticated users to use important resources (Margaret).

There are several methods of authentication (Darril) such as something you know (password or PIN), something you have (smart card, common access card (CAC) (DeBow and Syed 2016), personal identity verification (PIV) (Kittler et al. 2002), or RSA token (Vangie)), and something you are (using biometrics). Password or PIN authentication and different kinds of smart cards and tokens are easy to implement but because of this ease can be very easily stolen or lost. Biometrics is a new technological alternative to solve this problem (Jain et al. 1999). These typical biometric authentication technologies have some disadvantages (Erden). Therefore, a new biometric method needs to be produced to reduce the number of disadvantages that are within current systems. Brain signal is a human's characteristic, which does not have the problem of visibility to copy it, and it does not have the disadvantages of other biometric systems if the authors could employ it as a biometric authentication. Human brain signals are one of the characteristics that, nowadays, scientist and researchers are working on using brain-computer interface (BCI). BCIs are systems that provide communications between human beings and machines.

In the past, people always liked to read each other's mind or it was a wish for them to control their environments or replace objects with their brainpower. Today technology made those dreams happen. For instance, transfusing signals straight to someone else's brain to allow them to experience new sensory inputs like sight, hearing or feel. One of the potential outcomes of the future could be the manipulation of computers and associated devices with the simple transferring of a thought. Considering this potential BCI could be a very significant breakthrough within technology. BCIs are becoming increasingly popular in medical and non-medical areas as a way of communication to be conducted between humans and machines. Nowadays brain signal authentication using BCI devices is one of the popular subjects for researchers.

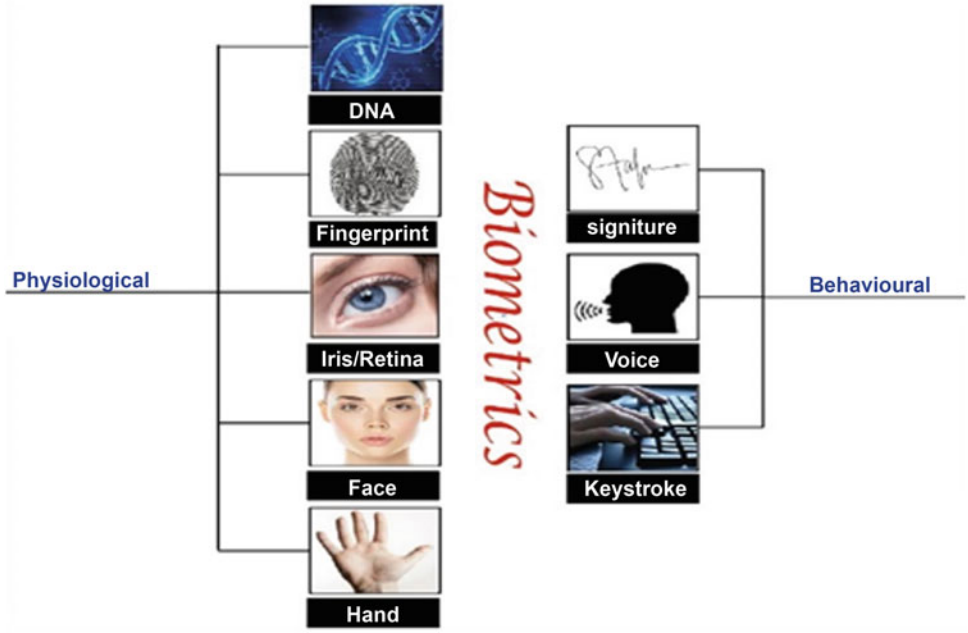
This article is a survey about biometric authentication techniques and using brain signals via BCI technologies as a new biometric authentication technique of a human body, which could be the most secure technology in the future.

Overview on EEG Signals

A review about biometric authentication in a couple of research papers and a literature review about BCI and brain signal authentication from the previous experiences of the other researchers, which are categorized to different subjects and goals, are as follows:

Biometrics

The word biometrics is a combination of two Greek words, "bios" (life) and "metrikos" (measure). This technology is mostly used for access control and identification or for identifying people who are under investigation (Faundez-Zanuy 2006). There are two different concepts in biometrics, which the authors should concentrate on, behavioral/physical biometrics and authentication/identification. Behavioral biometrics concentrates on analyzing the non-physiological or non-biological structures of any human. It studies the unique psychological characteristics of humans like signature, voice, gait, and



Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Fig. 1 Physiological and behavioral biometric types

keystrokes. Physical biometrics is doing the opposite, which is focusing on analyzing the physiological and biological structures of the human (Agrafioti et al. 2009). As you can see in Fig. 1, there are a couple of different behavioral and physiological human biometric types.

Biometric Authentication Types, Advantages, and Disadvantages

A biometric technique can work in two modes, authentication and identification, which are the heart of the biometric science (Prasanna et al. 2012). Biometric authentication is one of the most popular ways to provide personal identification because these characteristics of a human are specific and unique. Most of these specific features are so hard to duplicate and accurately produce (Kodituwakku 2015). In terms of information security, physiological biometric traits appear more practical. The most popular physiological biometric techniques are as follows:

Face Recognition

In comparison with the different biometric identification techniques, "face recognition is one of the most flexible, working even when the subject is unaware of being scanned" (Jafri and Arabnia 2009). It works by methodically analyzing particular characteristics that are common to human's face such as the size of the nose, the space between the eyes, position of cheekbones, jawline, and so forth (Margaret, Facial recognition). Table 1 shows some specific advantages and disadvantages of this biometric technique (Masupha et al. 2015).

Fingerprint Identification

Fingerprints are the most famous biometric which remain constant throughout life. It is more than 100 years in worldwide fingerprint comparison that no two same fingerprints were found. "Fingerprint identification involves comparing the pattern of ridges and furrows on the fingertips, as well as the minutiae points (ridge characteristics that occur when a ridge splits into two, or ends) of a specimen print with a database of prints on file" (Kute and Kumar 2014). Table 2 shows some specific advantages and disadvantages of this biometric technique (Tarun).

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 1 Face recognition biometric advantages and disadvantages

Face recognition	
Advantages	Disadvantages
Prevent card counters, etc. from entering casinos	Isn't accurate at all times
	Hindered by masks, glasses, long hair, etc.
Identify criminals, terrorists, etc.	Pictures must be taken when the users have a neutral face
Find missing people	"Considered an invasion of privacy to be watched"
Prevents elector frauds	
Targets shoppers	Easy to abuse

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 2 Fingerprint biometric advantages and disadvantages

Fingerprint identification	
Advantages	Disadvantages
It is one of the most developed biometrics	It needs more computer memory to store scanned data
Very high accuracy	
Easy to use	
Is the most economical biometric PC user authentication technique	Using the fingerprint scanner does not take into consideration when a person physically changes
It is standardized	
Small storage space required for the biometric template, reducing the size of the database memory required	It can make mistakes with the dryness or dirtiness of the finger's skin, as well as with the age (is not appropriate with children, because the size of their fingerprint changes quickly)

Retina Scan

In the backside of the eyeball, there is a layer of cells, which is the retina. This part of the eye converts light into nerve signals. To replicate a retina, there is no known way discovered. The pattern of the blood vessels at the back of the eye is unique. It stays the same for the whole lifetime (Choraś 2012). Table 3 shows some specific advantages and disadvantages of this biometric technique (Jatin).

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 3 Retina biometric advantages and disadvantages

Retina scan	
Advantages	Disadvantages
Like fingerprints, retina traits remain stable throughout life	Retina scan enrolments take longer than both iris scan and fingerprinting
Its resistance to false matching or false positives, regarding to pupil movements	Users claim discomfort with eye-related technology in general and the fact that retina scan technology has limited uses
The eye from a dead person would deteriorate too fast to be useful, so no extra precautions have to be taken with retinal scans to be sure the user is a living human being	Users commonly fear that the device itself or the light inside the device can harm their eyes in some way
	Users claim discomfort with the fact that they must position their eye very close to the device
The retina is located deep within one's eyes and is highly unlikely to be altered by any environmental or temporal condition	Many also feel that these retina scans can be linked to eye disease

Iris Scan

Iris is another part of the eyes, which has complex patterns that are stable, unique, and, in compare to the retina, can be observable from a long distance. The pattern-recognition method in Iris Scan process is using video images from a person's iris. In iris identification, the probability of error is the lowest of all biometrics. (Shekar and Bhat 2015). Table 4 shows some specific advantages and disadvantages of this biometric technique (Biometrictoday).

Current Biometric Technique Advantages and Disadvantages

Biometrics have too many different techniques and methods. After investigating some of the physiological biometric methods and the specific advantages and disadvantages of them, the authors are going to peruse the current biometric technique's advantages and disadvantages. Table 5 shows advantages and disadvantages of recent biometric methods (Le and Jain 2009).

Brainwaves as a New Biometric Authentication

The potential for using brainwaves as human biometric identification has risen to the surface once

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 4 Iris biometric advantages and disadvantages

Iris scan	
Advantages	Disadvantages
Scalability: This technology is highly scalable and can be used in both large- and small-scale programs	**Distance:** Iris is small and cannot be located from a few meters distance
Accuracy: Iris recognition is one of the best biometric modalities in terms of accuracy	**Expensive:** Iris scanners are relatively higher in cost compared to other biometric modalities
Stable: Iris patterns remain stable throughout an individual's life. It is protected by the body's own mechanism	**Infrared light:** The constant use of this system may cause harm to the iris because it is constantly being scanned with infrared light
Noninvasive: Iris recognition can be done with simple video technology. No use of laser technology is necessary to scan the iris making it a noninvasive technology altogether	**Movement:** A person has to be steady in front of the device to be enrolled by iris scanners. It means this device cannot be used like face recognition devices to scan anybody, regardless of their movements
Easy to use: Iris recognition system is plug and play compared to other modalities of biometric recognition. A person needs to stand still in front of the camera, and the job is done instantly. It is a comfortable process for everyone	**Obscure:** Eyelashes, lenses, and reflections, which create a problem, more often than not, obscure it
Fast: With iris recognition system, a person can complete the process within just a few seconds	**Reflection:** In some cases, it is hard to perform an iris scan due to the presence of reflections. It could happen in case of eyelashes, lenses, and anything in general that would cause a reflection
Traceable: The encoding and decision making of iris pattern is traceable. It takes only 30 milliseconds for the image analysis and the subsequent encoding	**Memory space:** A lot of memory is required for the data to be stored and later accessed
	Transformation: Iris may deform nonelastically as the pupil may change its size due to medical or other conditions

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 5 Biometric methods' advantages and disadvantages

Biometric advantages and disadvantages	
Advantages	Disadvantages
Convenient: The credentials are with human forever, so it does not require you to memorize or note down anything	**Physical traits are not changeable:** Users can reset a password, but they never can change their fingerprints or retina; these are fixed
Security: Biometric technology brings different types of solutions, which are nearly impossible to hack unlike passwords	**Unhygienic:** In contact-based biometric techniques, a biometric device is used a lot of times by enormous amount of people. Everyone is actually sharing his or her germs with each other via the device
Scalability: Unlike other solutions, biometrics are highly scalable solutions for all types of projects. It is possible for any kinds of projects because of the scalability of its solutions	**Error rate:** Usually, biometric devices make two types of errors, false acceptance rate (FAR) and false rejection rate (FRR) (Wayman et al. 2005). When the device accepts an unauthorized person, it is known as FAR, and when it rejects an authorized person, it is known as FRR
Accuracy: Biometric works with individual's physical traits such as fingerprints, face, and retina among others that will always serve you accurately anywhere, anytime	**Delay:** Some biometric devices take more than the accepted time and a long queue of workers form waiting to be enrolled in large companies
Flexibility: People have their own security credentials with you, so you do not need to bother memorizing awkward alphabets, numbers, and symbols required for creating a complex password	**Environment and usage matters:** Environment and usage can affect the overall measurements taken
Save money: With a little money, any company can track their employees and reduce the extra costs they are paying for years	**Physical disability:** Some people are not fortunate enough to be able to participate in the enrolment process. They might have lost or

(continued)

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 5 (continued)

Biometric advantages and disadvantages	
Advantages	Disadvantages
	damaged body parts such as fingers or eyes
Save time: Biometric solutions are highly time conserving	
Trustable: Reports claim that the young generations trust biometric solutions more than other solutions	

again, an idea presented as a way to distinguish humans with thoughts. Before becoming a method of security, it could be the measuring standard for biometric identification in the near future, but it needs more time and work on it. Brain signal can be one of the most practical biometric authentication methods (Fig. 2). It is obviously a possible technique of identification, and in terms of security, it could have a big role to play in the feature.

Neural Oscillations (Brainwaves)

Neural oscillations or brainwaves are an essential mechanism to enable the synchronization of neural activity inside and around brain areas and help the accurate temporal organization of neural processes underlying memory, cognition, behavior, and perception (Neustadter et al. 2016). "The interaction between neurons can give rise to oscillations at a different frequency than the firing frequency of individual neurons" (Roux and Uhlhaas 2014).

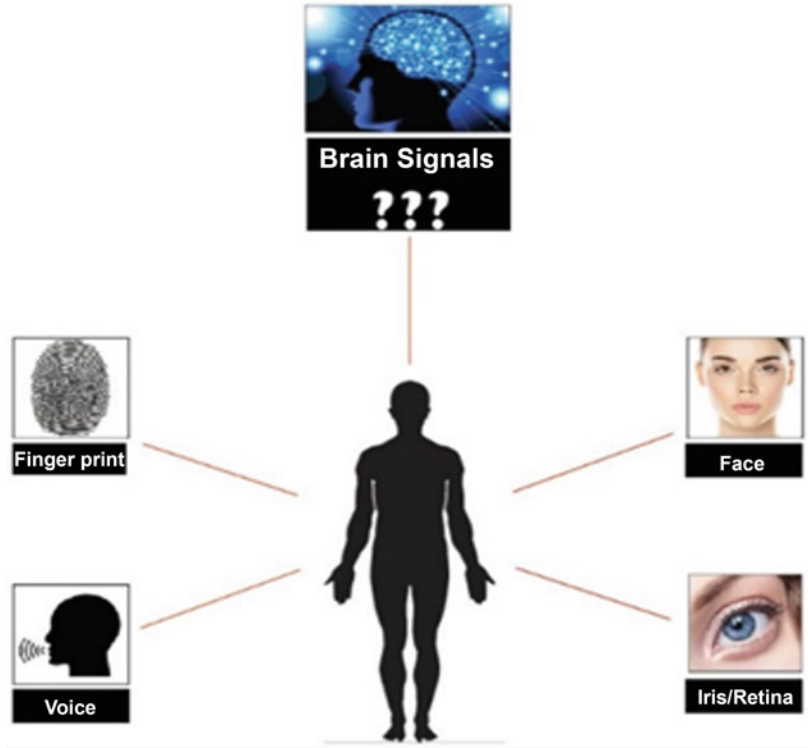
Electroencephalography (EEG)

Hans Berger was a German psychiatrist who observed the first human neural oscillations as early as 1924. He invented electroencephalography (EEG) for the recording of "brainwaves" by measuring electrical activity in the patient's brains in the hospital which had a skull damage (Millet 2002). EEG is one of the techniques for brain imaging. Table 6 shows the different brain imaging techniques (Imotion EEG packet guide).

Electroencephalography (encephalon = brain) or EEG is an electrophysiological observing technique to capture electrical activity generated by the brain from electrodes placed on the scalp surface (Niedermeyer and da Silva, 2005). "EEG refers to the recording of the brain's spontaneous electrical activity over a period, as recorded from multiple electrodes placed on the scalp" (Niedermeyer and da Silva 2005). Many of the brain's emotion recognition techniques have been implemented and proposed for the last few years which most of them involved the extraction of EEG signals (Abuhashish et al. 2015). In comparison to other imaging methods, EEG has some benefits. It is an excellent tool for studying the processes of neurocognitive underlying person behavior because of some reasons such as the following: (1) EEG has very high time resolution and captures cognitive processes in the time frame in which cognition occurs. (2) EEG directly measures neural activity. (3) EEG is inexpensive, lightweight, and portable. (4) EEG monitors cognitive-affective processing in the absence of behavioral responses (Catarino et al. 2011). In terms of frequency, there are five types of brainwave (gamma, beta, alpha, theta, delta), and "each frequency is measured in cycles per second (Hz) and has its own set of characteristics representing a specific level of brain activity and a unique state of consciousness" (Korde and Paikrao 2018). This is represented in Table 7. According to the types of brainwaves, four different kinds of mental activities such as movement, emotions, talking, and motor imagery have been measured by investigators (Abuhashish et al. 2014).

Brain-Computer Interface (BCI)

"Brain-computer interface is a method of communication based on neural activity generated by the brain and is independent of its normal output pathways of peripheral nerves and muscles" (Vallabhaneni et al. 2005). BCIs are developed by the research community with some applications in mind to the generation of new assistive devices (Rao and Scherer 2010). Brain-computer interface technology is a powerful communication tool for both users and systems. "The BCI has the capacity to access brain activities and impart relevant



Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Fig. 2 Brain signals beside the most practical biometric authentication techniques

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 6 The methodology of brain imaging techniques and the ways that they work

Brain imaging techniques		
Methodology	What is imaged?	How?
Electroencephalography (EEG)	Changes in electrical brain current	Electrodes placed on scalp measure electrical brainwaves
Positron emission tomography (PET)	Emissions from radioactive chemicals in the blood	Radioactive isotopes injected into the blood are detected like X-ray
Computed (axial) tomography scan (CT or CAT)	X-ray images of the brain	Multiple images (tomograms) are taken by rotating X-ray tubes. Doesn't image function
Functional magnetic resonance imaging (fMRI)	Blood flow; oxyhemoglobin-to-deoxyhemoglobin ratio	Relies on the magnetic properties of blood. Shows brain function spatially and temporally
Magnetoencephalography (MEG)	Changes in electrical brain current	Similar to EEG but magnetic brainwaves are measured instead of electrical brainwaves

information on the emotional status of the user" (AbuHashish 2015). There is no need for any external devices or muscle involvement to issue instructions and complete the communication (Bi et al. 2013). Normal individuals have been targeted in most recent studies by exploring the use of BCIs as an input device and exploring the generation of hands-free applications (van Erp et al. 2012).

BCI Types

The BCI can be separated into invasive, partially invasive, and noninvasive types (Abhang et al. 2016). In invasive BCI, recording the signals occurs when electrodes enter the brain tissue. This is a permanent basis method, which buries electrodes within the brain. Partially invasive BCI is a process in which electrodes are placed inside

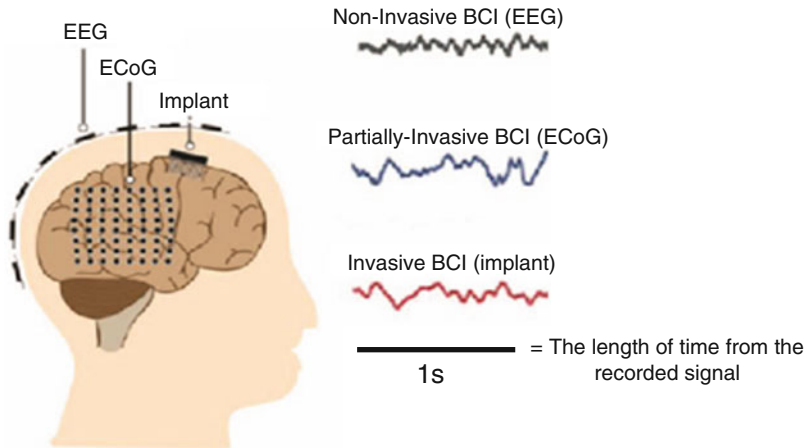
of the skull but rest outside the brain rather than within the gray matter above the brain's surface. A good example for partially invasive BCI is electrocorticography (ECoG). ECoG is a type of monitoring that uses electrodes placed directly on the bare surface of the brain to record brainwaves from the cerebral cortex (Palmini 2006). In non-invasive type of BCI, no surgery is needed. Instead, the sensors or electrodes are placed over the head (via a hat, belt, patch, or a headset) to measure electroencephalography (EEG), which reads the rhythm of brain activities (Mayoclinicstaff Electromyography (EMG)). There are many brain devices that are used to capture brain activities. These devices are brain controllers, which are very common technologies in the BCI area that can read the electrical brain functions (Abuhashish et al. 2015b). The following image (Fig. 3) shows the different layers of the brain and where the signal is taken from by three different methods such as EEG, ECoG, and implant.

BCI System Process

A BCI is a system that can distinguish a definite set of forms in brain signals following five sequential stages (Fig. 4): signal acquisition, preprocessing or signal enhancement, feature extraction, classification, and the application interface (Khalid et al. 2009). You can see in Fig. 4 that the first part of BCI process starts with acquiring the signals from the brain and goes to the next section,

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 7 Types of brainwaves and their frequency rates and mental state situation

Wave	Frequency	Mental state
Gamma	Above 40 Hz	Thinking, integrated thought
Beta	13–40 Hz	Alertness, focused, integrated, thinking, agitation, aware of self and surroundings
Alpha	8–12 Hz	Relaxed, non-agitated, conscious state of mind
Theta	4–7 Hz	Intuitive, creative, recall, fantasy, dreamlike, drowsy, and knowing
Delta	0.1– 4 Hz	Deep, dreamless sleep, trance, and unconscious

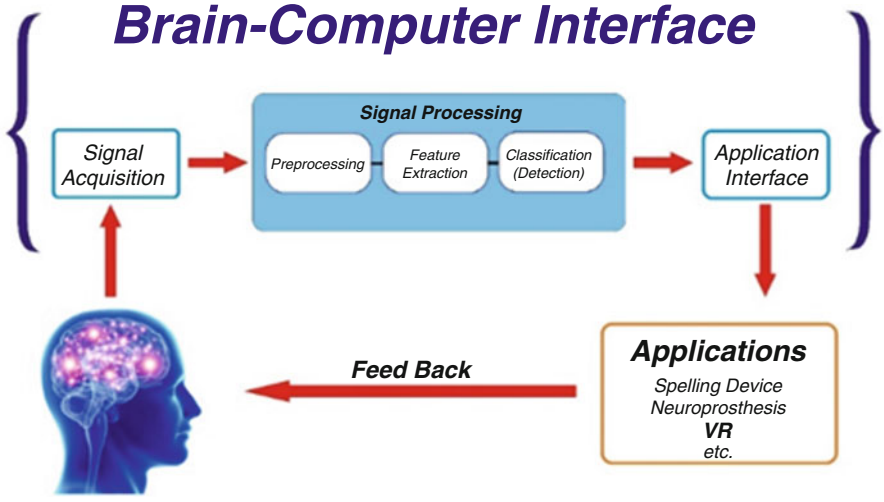


Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Fig. 3 The way that BCI captures the signals from the human brain (Mayoclinicstaff Electromyography (EMG))

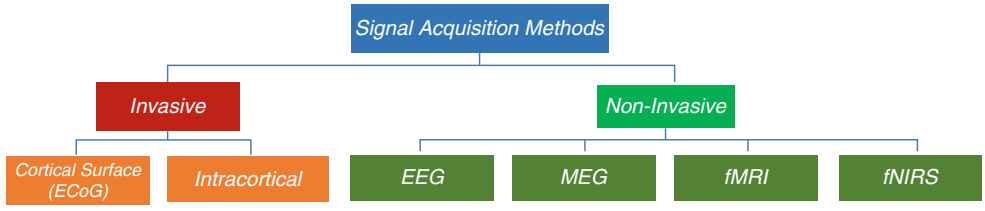
which has three subsections for signal processing to make the signal ready to use in different applications and for different purposes.

Signal acquisition is a considerable challenge in the field of BCI. Some methods focus on EEG signals; however, other methods exist that can capture neurological activity. End use is a factor that is intended by the designer which filters out which method you should use for capturing specific signals (Major and Conrad 2014). Different methods for signal acquisition have been studied. There are two general classes of brain acquisition methods, which are invasive and non-invasive (Fig. 5). Each method is using different types of BCI devices.

After signal acquisition part, signals are going to be preprocessed. Signal preprocessing is also called signal enhancement (Norani et al. 2010). In general, the acquired brain signals are unclear by noise and artifacts. The artifacts are eye blinks, eye movements, and heartbeat. In addition to these, muscular movements and power line intrusions are also mixed with brain signals (Bin et al. 2009). A couple of different methods are used for artifact removal which "the most frequently used methods are Common Average Referencing (CAR), Surface Laplacian (SL), Common Spatial Patterns (CSP), Independent Component Analysis (ICA), Principal Component Analysis (PCA) and Adaptive Filtering" (Lee et al. 2010). Overall, these techniques have specific purposes that could match each objective of experiments conducted (Mallick & Kapgate, 2015).



Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Fig. 4 Brain-computer interface process



Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Fig. 5 Brain signal acquisition's methods

After preprocessing and filtering, the EEG signals will pass through feature extraction process and select particular features by some feature selection methods. Some researcher used a hybrid BSS-SVM system to extract the movement-related features from the EEGs (Peterson et al. 2005). In most existing BCI, this identification relies on a classification algorithm. Using classification algorithms is the most popular tactic for this purpose. These procedures are used to identify "patterns" of brain activity (McFarland et al. 2006).

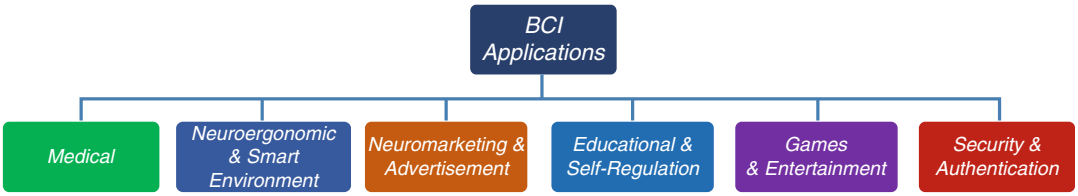
Classification algorithms divided into five different categories: linear classifiers, neural networks, nonlinear Bayesian classifiers, nearest neighbor classifier, and combinations of classifiers (Lotte et al. 2007). BCI has many applications, especially for disabled persons. It reads the signals generated by the brain and translates them into activities and commands that can control the computers (Lotte 2006). Figure 6 shows the different types of BCI applications.

BCI Security Authentication Using EEG Signals

As the authors mentioned before, a couple of different ways are there which are designed for acquiring the brain activities noninvasively, including magnetoencephalography (MEG), functional magnetic resonance imaging (fMRI), positron emission tomography (PET), near-infrared spectroscopy (NIRS), and electroencephalography (EEG). In comparison to other methods, EEG is a noninvasive method, which is not very expensive and allows recording the signals passively. EEG-based user authentication systems are currently popular in BCI security and authentication applications. Recently, scientists and researchers have been doing many attempts to observing the pattern uniqueness of the brain signal. Several different methods have been used to analyze EEG signals. In regard to the recent progression of EEG signal acquisition devices, the capability of providing better results is going higher, and these processes are getting simpler. The authors are going to review a couple of different tactics of EEG capturing methods to acquire better accuracy and check the applicability of using signal authentication purposes. There are four different studies in this research area that were more successful and reported better accuracy in their experiences (Jayarathne et al. 2017) which are linear discriminant analysis (LDA), cosine similarity → LDA, power spectral density (PSD) and spectral coherence (COH) → Mahalanobis distance and match-score fusion, and event-related potentials (ERP). These studies used different tasks, extracted features, and classifiers for doing their experiments to get higher accuracy rates of brainwaves to use them for authentication purposes. Besides the studies mentioned above, Table 8 summarizes some other studies with achieved accuracy and other characteristics. Generally, accuracy of each system depends highly on these aspects.

Discussion

Recent biometric user authentication techniques have some problems and limitations. To cover the recent biometric limitations, we need a new biometric brainwave-based authentication, which is another technique in the extensive range of authentication systems. There are many



Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Fig. 6 BCI application fields

Brain Signals as a New Biometric Authentication Method Using Brain-Computer Interface, Table 8 Summary of various studies (in decreasing order of accuracy) (Jayarathne et al. 2017)

Author(s)	Channels	No. of subjects	Task	Derived or extracted feature	Classifier	Avg. accuracy
Rui-Blondet et al.	3	50	Visual simulation of 400 images	Event-related potentials (ERP)	Normalized cross-correlation	100%
La Rocca et al.	64	108	Relaxation with opened eyes and closed eyes	Power spectral density (PSD), spectral coherence (COH)	Mahalanobis distance-based classifier and match-score fusion	100%
Chen et al.	16	29	Rapid serial visual presentation (RSVP)	Point-biserial correlation coefficients, Fisher's transformation	Linear discriminant analysis (LDA)	100%
Palaniappan	6	6	5 tasks: relaxation, math activity, geometric figure rotation, mental letter composition, visual counting	Auto-regressive coefficients (AR), spectral power (SP), inter-hemispheric power differences (IHPD), inter-hemispheric linear complexity (IHLC)	LDA	100%
Ashby et al.	14	5	4 tasks: relaxation, limb movement, geometric figure rotation, visual counting	AR, SP, IHPD, IHLC, PSD	Support vector machine (SVM)	100%
Chuang et al.	1	15	7 tasks: breathing, simulated finger movement, sport activity, singing/ passage recitation, audio listening, color identification, and pass-thought	Cosine similarity of the vector representation	k-Nearest neighbor (k-NN)	99%
Palaniappan	61	20	Drawing of common objects as visual simulation	Multiple signal classification (MUSIC)	k-NN, Elman neural network (ENN)	98%
Riera et al.	4	–	Relaxation	AR, fast Fourier transform (FFT), mutual information, coherence, cross-correlation (EEG and ECG data)	Fisher discriminant analysis (FDA)	98%
Jayarathne et al.	14	12	Imagining four-digit number as cognitive task	Common spatial patterns (CSP)	LDA	97%
Liew et al.	8	10	Apprehension of images as visual simulation	Coherence, cross-correlation, mean amplitude	Fuzzy-rough nearest neighbor (FRNN)	92%
Yeom et al.	18	10	Apprehension of images of faces including self-face as visual simulation	Difference of average signals, positive/ negative peaks at specific latencies	Nonlinear SVM classifier	86.1%

researches about brain signal patterns and using them as a person authentication. Electroencephalogram (EEG) signals are the most popular method in this process. A couple of different approaches are presented in this way to capture EEG signals and classify them with different classification methods to find the unique signals and use them as an authentication method with more accuracy.

Chen et al. (2016) proposed a system within authentication, which is centered on rapid serial visual presentation (RSVP) stimulus. A brain amplifier was used to obtain EEG signals and linear discriminant analysis (LDA) to classify them. A specific association constant calculated the important features. According to the author's notation, a password can be hidden effectively in certain compulsive situations.

Chuang et al. (2013) presented a new approach which used the MindWave to obtain data. Seven tasks were executed, including sports activity, breathing, audio listing, simulation of finger movement, color, reciting and identifying music with singing, and pass-thoughts. The classification process is done with the k-nearest neighbor (k- NN) algorithm. The most accurate strategies were for color, audio, and sport. The most difficult one was for the pass-thought task according to the results of the questionnaire that determined user-friendliness with different tasks. Breathing, audio, and color were the straightforward tasks.

La Rocca et al. (2014) presented an approach centered around connectivity within EEG spectral coherence. In this method, data samples were gathered from 108 participants during open resting and closed eyes positions. EEG data was captured using a system consisting of 64 different channels with a rate of 160 Hz. Data was filtered to 50 Hz via a low-pass anti-aliasing filter. Spectral coherence (COH) and power spectral density (PSD) analysis techniques were used to extract mental features. To calculate uniqueness, two different algorithms were used separately in this process which were Mahalanobis classifiers that were based on distance and match-score fusion system. This technique is strong and very accurate for user identification. The performance of classification has the possibility of not functioning properly if this classification was used for a larger group of users on traditional hardware and it is less than 100%.

Ruiz-Blondet et al. (2016) presented a protocol known as CEREBRE with a band-pass filtering between 1 and 55 Hz, and based on normalized cross-correlation, a simple discriminant function was used for classification. The nominal (four categories, three channels) classifier showed the highest accuracy when all the patterns were used, but both maximum and minimum classifiers showed 100% accuracy. The results presented that the most accurate was for the stimulus oddball and food. The resting pattern had a reduced performance in terms of classification. Authentication centered on a memory-evoking task (also known as "pass-thoughts" in other studies) (Thorpe et al. 2005) also showed weak results; this is due to the inconstant time that was consumed to allow thinking.

According to the limitations of the methods which have been presented in the published papers and researches, the authors need better techniques like using different tasks and user strategies to acquire brain signals, better methods for preprocessing and feature extraction, and better classifiers to find the unique brain signal and use it as a new biometric authentication.

Conclusion

In the near future, biometric authentication methods will be the most useful methods for devices and applications for security because of the usability and security level and they are easier to use. However, there are some disadvantages for some methods. Brainwave is another human biometrics. There were some experiments using brain signals as an authentication method, which in some methods high accuracy is acquired. However, they had some limitations, which can be improved in the future.

Brainwaves are another human biometric that could be the most secure biometric technique. In comparison with other biometric techniques in terms of security, the human brain signal has a couple of important advantages. It is the only biometric that is changeable, it is not visible to

duplicate and does not have shoulder surfing problem, and it is more useful for disabled people in which a good example would be the famous scientist Stephen Hawking who was using a kind of brain-computer interface technology.

Definition

B-Splines are one of the most promising curves in computer graphics. They are blessed with some superior geometric properties which make them an ideal candidate for several applications in computer-aided design industry. In this entry, some basic properties of B-Spline curves are presented. Two significant B-Spline properties, viz., convex hull property and repeated points' effects are discussed. The B-Splines' computation in computational devices is also illustrated. An industry application based on image processing where B-Spline curve reconstructs the 3D surfaces for CT image datasets of inner organs further highlights the strength of these curves.

Introduction

Before the evolution of computer graphics, the aircraft wings and automobile parts were designed through splines. A spline constitutes long wood or plastic pieces of flexible nature where rectangular section is put in place at several positions using heavy lead weights commonly known as ducks. The duck places the spline at fixed positions with respect to the drawing board (Beach 1991). This helps spline to take the natural shape considering ducks. The spline's shape can be changed through ducks' movement. This has several drawbacks such as duck positions recording, drafting equipment required towards complex parts, consumer costs, absence of closed form solutions, etc. (Buss 2003).

As such, polygons give good rendering. But a better way is required towards generating the curved surfaces. For a designer, it is difficult to manipulate directly billions of polygons which make up the rendered model. A general way is required to specify arbitrary curved surfaces that can be converted to rendering polygons. For this, a mechanism is required which allows to specify any smooth desired curved surface. The solutions are generally provided by three categories of surfaces, viz., Bézier surfaces, B-Spline surfaces, and subdivision surfaces. In this direction, the computer-aided design industry uses NURBS surfaces as its standard definition mechanism. The visual effects industry uses both NURBS and subdivision surfaces. With the introduction of UNISURF which is a CAGD software tool by Pierre Bezier (https://en.wikipedia.org/wiki/Pierre_Bézier), the smooth curves can be easily projected on screens and monitors at low physical storage space. This resulted in the evolution of various CAD based software such as Maya, Blender, 3DMax, etc. This followed the development of a new mathematical structure called spline which is a smooth curve represented through few points.

With this motivation, in this entry, we present the basic properties which define the B-Spline curves. Some of the significant B-Spline properties discussed here are convex hull property and repeated points' effects. The computation task for B-Splines in computational devices is also highlighted. An industry application revolving

around image processing with B-Spline applications on 3D surface reconstruction towards inner organs taken from CT images further highlights the significance of these curves. This entry is organized as follows. Section "B-Splines: Overview" gives an overview of the B-Spline curves with computation task for these curves. This is followed by an industry application involving image processing with B-Splines. Finally, the conclusions are given.

B-Splines: Overview

The B-Splines are highly capable for describing various forms of curves (Chaudhuri 2018). They form a special case for splines, to be more specific the Bezier curves generalization. They are constructed with orthonormal basis of recursive functions. They comprise of curves which are of polynomial nature at points which are basically knots. The polynomial's degree is identical to that of B-Spline. The cubic segments form an important part of B-Splines. Such curves are known as cubic B-Splines. Now we present some B-Splines along with certain examples highlighting the special scenarios.

Considering a, b, c coordinates with respect to parameter t, B-Spline can be represented as: $a = a(ts)$, $b = b(ts)$, $c = c(ts)$. For B-Spline parametric curve, there exists certain discontinuities for parametric functions at parameter values which depict the knots. For B-Spline, there are several polynomial curve sections as control points number minus polynomial's degree. Considering N control points and n^{th} degree polynomial, there exists $(N - n)$ sections. The joining of these sections happens at $(N - n - 1)$ knots. For control points $\overline{cp}_i; i = 1, \ldots\ldots, N$ with $\overline{cp}_i = \langle x_i, y_i, z_i \rangle$. For polynomial curve's dimensionality connecting knots being n, then B-Spline's parametric equation is:

$$\bar{V}(ts) = \sum_{k=1}^{N} BS^{n}_{(k-1)}(ts)\overline{cp}_k \; ts_n \leq ts \leq ts_N, \quad N \geq n+1 \tag{1}$$

The knots should have parameter values ts along with them. The ts values at knots are represented as ts_{j+n} considering knot joint of $j^{th}$and $(j + 1)^{th}$ polynomial segments. This is in addition to the parameter values ts_n and ts_N which correspond towards start and end for complete curve. There are also $2n$ parameter values $ts_0, \ldots\ldots, ts_{n-1}$ and $ts_{N+1}, \ldots\ldots, ts_{N+n}$ values which are associated blending polynomials. The values ts_j are monotonically increasing values which may be either equally spaced, integers or positive.

The functions $BS^n_k(ts)$ are recursively defined as:

$$BS^n_k(ts) = \frac{ts - ts_k}{ts_{k+n} - ts_k} BS^{n-1}_k(ts) + \frac{ts_{k+n+1} - ts}{ts_{k+n+1} - ts_{k+1}} BS^{n-1}_{k+1}(ts) \tag{2}$$

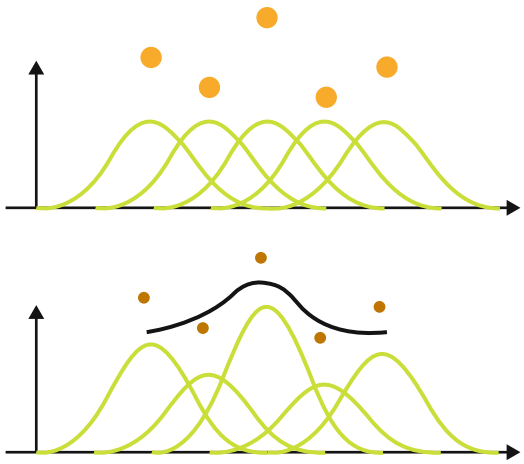
With unit step function being defined as:

$$us(ts) = \begin{cases} 1 & ts > 0 \\ 0 & ow \end{cases} \tag{3}$$

The 0^{th} order polynomial BS is:

$$BS^0_k(ts) = us(ts - ts_k)us(ts_{k+1} - ts) \tag{4}$$

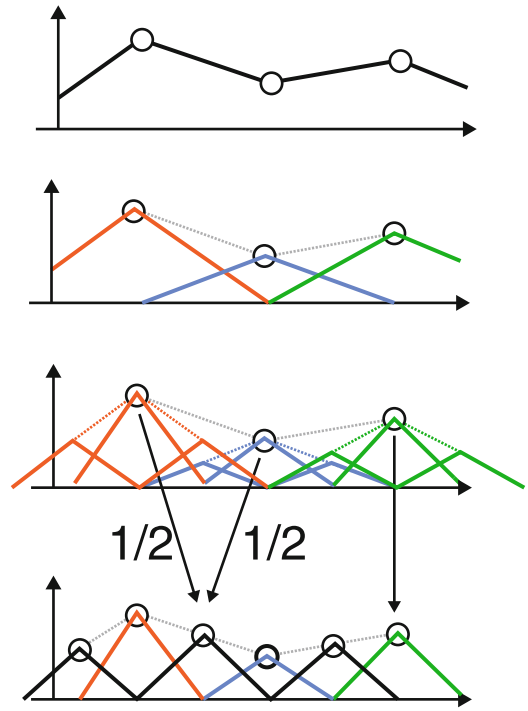
It is to be noted that $BS^n_k \neq 0$ considering range $ts_k < ts < ts_{k+n+1}$. Figure 1 illustrates



B-Splines, Fig. 1 Some representative B-Spline curves

some B-Spline curves. The B-Splines are basically characterized by the following properties:

(a) They can easily be represented through piecewise polynomial. This allows a B-Spline curve to be represented as a linear combination of number of B-Splines. Any B-Spline curve can be refined as linear combination of piecewise segments as shown in Fig. 2. The curves can also be refined through linear operation on control points.
(b) The unit integral can effectively represent a B-Spline as: $\int_{-\infty}^{+\infty} BS_k(ts)d(ts) = 1$.
(c) They are nonnegative in nature such that: $BS_k(ts) \geq 0$.
(d) B-Splines always partition of unity: $\sum_j BS_k(ts - j) = 1$.
(e) They are highlighted through the support factor: $BS_k(ts) \neq 0$, $ts \in [0, k]$.



B-Splines, Fig. 2 B-Spline curve refined as linear combination of piecewise segments

Now let us discuss some significant properties of B-Splines. The two important properties of B-Splines worth mentioning are the convex hull property and the effect of repeated points. The justifications are trivial in nature.

It is known that by recursion $BS_k^n > 0$, and it can also be shown for one n at a time. As a result of this, using recursion leads to:

$$\sum_{k=1}^{N} BS_{(k-1)}^n(ts) \equiv 1, ts_n < ts < ts_N \quad (5)$$

With this, B-Splines satisfy the convex hull requirements.

The B-Spline curve moves near the coordinate, when adjacent points of control have identical coordinates. Considering n identical adjacent control points, the spline interpolates the point.

Next, we consider the case where integer knots are equally spaced. Let us consider $ts_k = k$, then from the above equations we have:

$$BS_k^0(ts) = us(ts - k)us(k + 1 - ts) \quad (6)$$

$$BS_k^n(ts) = \frac{ts - k}{n} BS_k^{n-1}(ts) + \frac{k + n + 1 - ts}{n} BS_{k+1}^{n-1}(ts) \quad (7)$$

It is to be noted that $BS_k^0(ts) = BS_0^0(ts - k)$, such that by recursion $BS_k^n(ts) = BS_0^n(ts - k)$. Hence, for knots' integer spacing which results in B-Splines of uniform nature, only single blended polynomial is required towards each spline's degree.

Now some examples are highlighted for cubic B-Splines. The higher degree polynomials become:

$$BS_0^1(ts) = ts\{us(ts)us(1 - ts)\} + (2 - ts)\{us(ts - 1)us(2 - ts)\} \quad (8)$$

$$BS_0^2(ts) = \frac{1}{2}ts^2[\{us(t)us(1 - ts)\} + \{ts(2 - ts) + (3 - ts)(ts - 1)\}\{us(ts - 1)us(2 - ts)\} + (3 - ts)^2\{us(ts - 2)us(3 - ts)\}] \quad (9)$$

$$BS_0^3(ts) = \frac{1}{6}\left[ts^3\{us(ts)us(1-ts)\}\right.$$
$$+ \{ts^2(2-\mathrm{ts}) + ts(ts-1)(3-ts)$$
$$+ (ts-1)^2(4-ts)\}\{us(ts-1)us(2-ts)\}$$
$$+ \left\{ts(3-ts)^2 + (ts-1)(3-ts)(4-ts)\right.$$
$$+ (ts-2)(4-ts)^2\}\{us(ts-2)us(3-ts)\}$$
$$\left.+ \left\{(4-ts)^3 us(ts-3)us(4-ts)\right\}\right] \tag{10}$$

The graphical plots corresponding to the four lowest order blending polynomials are shown in Fig. 3.

With respect to the above equations, B-Spline can also be refined as linear combination of dilates and translates of the curve itself. This can be written recursively for $k = 0, 1$ as:

$$BS_0(ts) = BS_0(2ts) + BS_0(2ts-1) \tag{11}$$

$$BS_1(ts)$$
$$= \frac{1}{2}[BS_1(2ts) + 2BS_1(2ts-1) + BS_1(2ts-2)] \tag{12}$$

The above equations are represented through the curves shown in Fig. 4. Some of the refinement masks are also shown in Fig. 5.

The above equations are further generalized as follows:

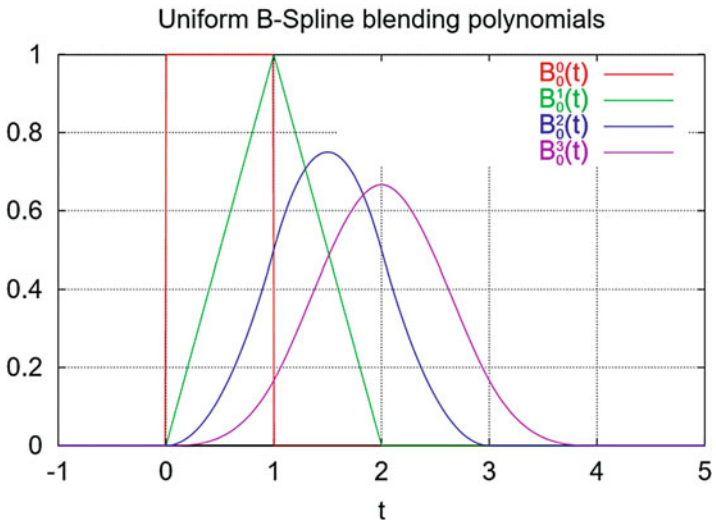
$$BS_k(ts) = \frac{1}{2^k} \times \sum_{k=0}^{n+1} \binom{n+1}{k} BS_k(2ts-k) \tag{13}$$

The subdivision operators can readily be applied on B-Splines. The subdivision works through bases and control points. Considering a B-Spline, subdivision operator S can be enforced such that:

$$BS(ts) = BS(2ts)S \tag{14}$$

The term S in above equation represents the subdivision matrix. Figure 6 represents a typical subdivision matrix. The subdivision operation is stationary in nature.

The subdivision can be successively applied on control polygon using control points' sequence. The subdivision in B-Splines leads the resulting curve to convergence, smoothness, and approximation. The subdivision matrix converges the curve towards cubic B-spline representation. This allows the control polygon to be drawn instead of the curve. Using an iterative refinement process, the curve approximation is achieved through several refinements as shown in Fig. 7.

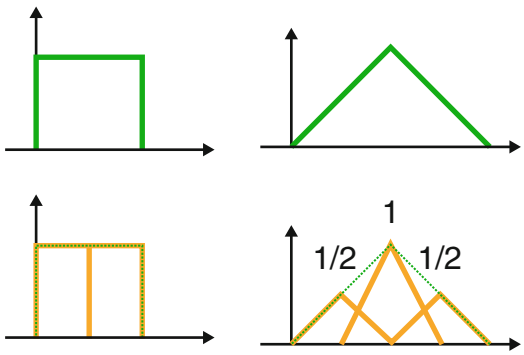


B-Splines, Fig. 3 The four lowest order blending polynomials corresponding to uniform B-Splines

The surface approximation is done using tensor product which is defined over regular quadrilateral meshes. Sometimes semi-regular quadrilateral meshes are used which have few sufficiently separated vertices. The semi-regular meshes represent the boundary surface of an object. In geometric modeling, patches of regular meshes are traditionally used and stuck together. But it becomes difficult towards handling patch density.

Computation Task for B-Splines

The B-Splines are generally computed through fast computing devices (Chaudhuri 2018) because small time steps are required by a smooth curve. To make the computations simple, the calculations are specified with respect to regular uniform B-Splines. Let us start considering the spline order. Considering the order as k, a set of n control points are specified. The number of points on the curve may vary depending on the smoothness desired by the user. These set of points are denoted as the curve set.

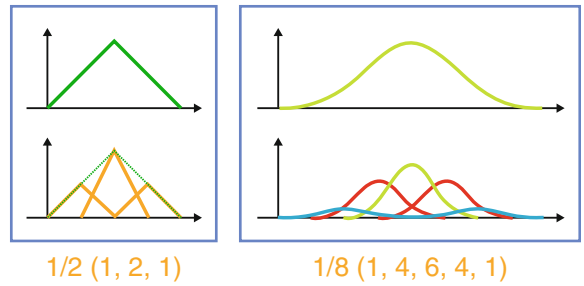


B-Splines, Fig. 4 The curves on left and right are represented through above equations

As the initial step, the uniform knot vector of length $n + k$ is considered. The calculation is performed as follows. Each knot is initialized as zero. Then considering each $1 < i \leq n + k$, it is required to be verified whether conditions $i > n$ and $i < n + 2$ are satisfied. If the conditions hold, then current knot takes the value of previous knot with an increment of 1 otherwise, the current knot considers the previous knot value. Now considering $k = n = 4$, the knot vector takes the value $\{0, 0, 0, 0, 1, 1, 1, 1\}$. Before calculating the curve set points, it is required to fix a correct step value for parameter *ts*. The step is reached by dividing knot's value considering one less than number of points on curve set.

Now we initiate the computing task towards curve set points for B-spline. Care should be taken such that the number of basis functions which are calculated for each time step is equal to that of number of points in control set. Thus considering the entire spline, number of basis computations is same as the product of magnitudes of control and curve sets. Hence for 20 points on curve set with 4 control points, 80 basis functions are required to be calculated.

At each step, Cox-de Boor algorithm is used in order to calculate the basis function's value. During each iteration through the steps, the entire knot vector is taken as with step value *ts*. It is observed that Cox-de Boor algorithm is recursive. As a result of this, care needs to be taken such that the basis is calculated correctly. When the set of n basis functions for control points at specified step *ts* is available, the curve points' coordinates are calculated by multiplying the i^{th} basis function to i^{th} control point. The values obtained are then embedded into curve set. This helps towards generation for collection of points which when plotted together as well



B-Splines, Fig. 5 The curves on left and right represent the refinement masks for $\frac{1}{2}(1,2,1)$ and $\frac{1}{8}(1,4,6,4,1)$

as connected with line segments resembles a curve. The number of calculations required to make B-spline are appreciably large.

Industry Application

In this section, a novel industry application involving B-Spline surfaces with image processing is presented which is adopted from Ref. (Partyka 2014). The experimental dataset contains about 1900 images from the CT scan of the entire body. Only 500 images considering the chest and upper abdomen have been used for analysis. Here 3D surface is reconstructed for organs developed through tomography. It uses k-means clustering and Hu moments in order to filter contours considering the tomography frames. The least squares B-Spline fitting approximates filtered contours. The organ surface is approximated through B-Spline surface. The technique requires no human intervention. As such, high-quality surfaces in versatile format are created.

The contour selection process is a significant step in surface reconstruction. Each contour is selected with utmost care. Then noise is minimized such that resulting surface is not affected. Also, a high-fidelity product needs to be maintained. Here enhancement of each CT slice done and canny edge detector detects the contours. An empirical threshold for edge detector is set. The morphological operations and filtering for small contours is done to eliminate unwanted noise. The effects of filtering are presented in the second and third images for the Figs. 8, 9, and 10.

The unwanted contours are removed through automatic noise filtering where larger datasets are created using contour detection. The right lung is taken as region of interest (RoI). About 1996, contours covering chest, left lung, stomach, aorta, etc. are created through contour detection and filtering step. The right lung is selected manually from 450 images. Because of shape and contours location diversity, these contours are filtered through k-means clustering. To address the contour's shape, an n-dimensional vector is created which is composed of (X, Y) coordinates for contour's centroid and varying Hu moments. After detecting and prefiltering contours, clustering is done. Considering each contour, Hu

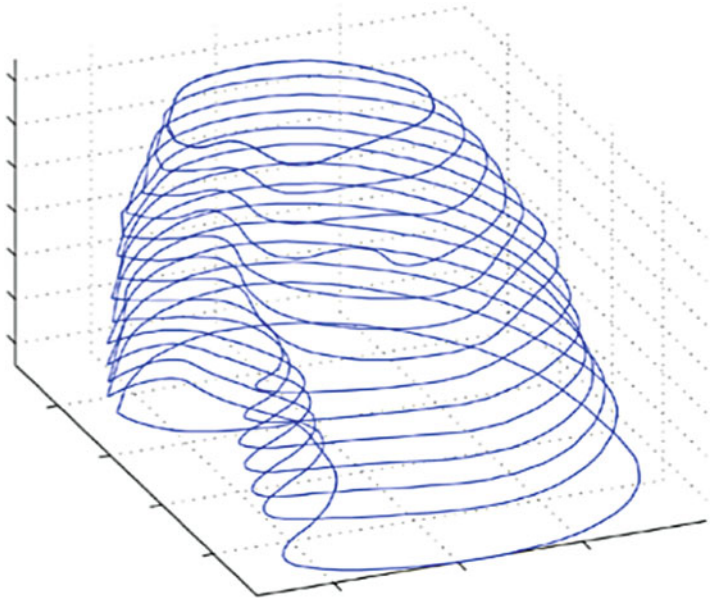
moments and centroid are calculated which are used after normalization towards k-means clustering. These clusters are used towards examined contours classification considering Euclidean distance from cluster which represents RoI. The testing is done for all combinations of feature vectors based on contour centroid as well as its Hu moments. The best results are achieved through second Hu moment with respect to centroid coordinates.

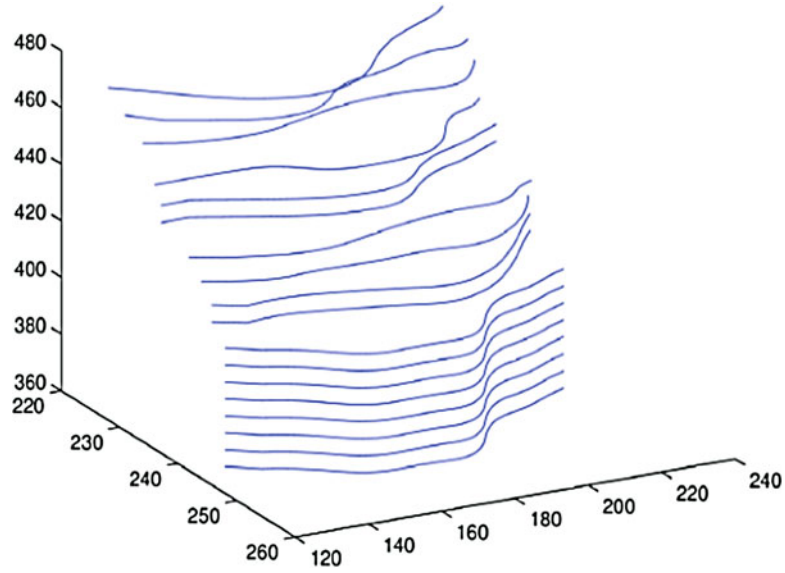
B-Splines, Fig. 11 The correctly classified contours

B-Splines, Fig. 12 The false +ves classified as contours

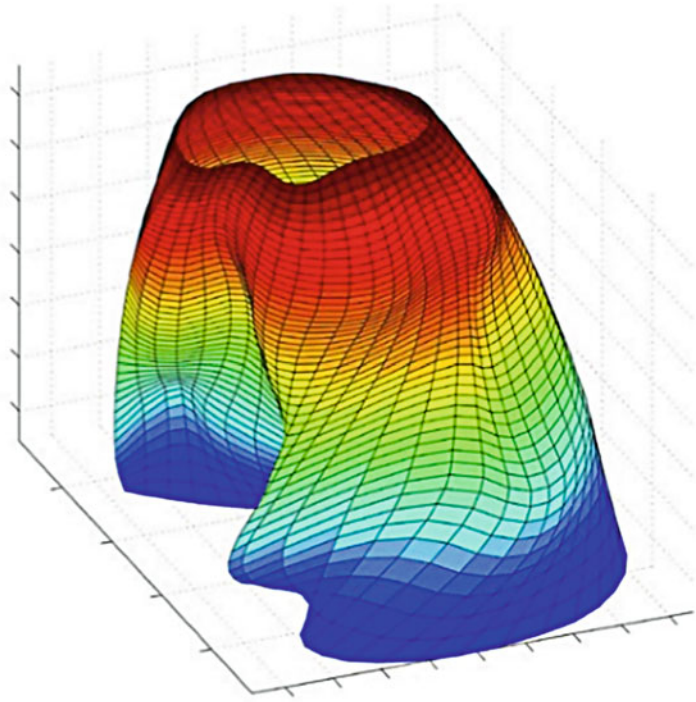
B-Splines, Fig. 13 The surface approximations through cross sections



The n-dimensional cluster centroids achieved during k-means are utilized towards segmenting the desired contours. Actually, good responses are received with 3D vectors where second Hu moment and (X, Y) coordinates for contour's gravity center are used. The experiments were done using 1996 labeled contours from which 450 are taken as right lung and others are ignored. Figures 11 and 12 show the correctly classified contours and false positives classified as contours, respectively. It is to be noted that second Hu moment



B-Splines, Fig. 14 The lung surface reconstructed through cross-section fragments



B-Splines, Fig. 15 The lung's twisted surface

alone with (X, Y) coordinates for contour's gravity center produces appreciable results. The 3D vector substantially reduces the calculations and yields faster and more responsive application.

After the contour segmentation, the algorithm is approximated and least-squares B-Spline fitting for every contour is done. The contour points in preceding algorithm steps are used towards fitting cubic B-Spline for every segmented contour cross section.

The curve points form the organ contour are in place and the control points are required to be computed. This can be represented as the following equation where CV, NB, and N denote the curve, orthonormal basis, and control points, respectively:

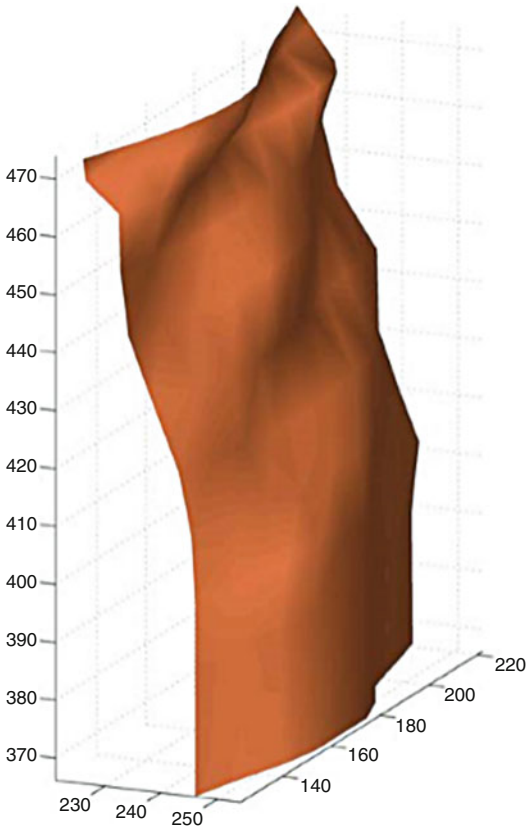
$$CV = NB \cdot N \tag{15}$$

The above equation can be solved towards N considering least squares such that:

$$N = \left(NB^T \cdot NB\right)^{-1} \cdot NB^T \cdot CV \tag{16}$$

The resulting N matrix comprises of control point vectors towards every cross section. To achieve a smooth surface, all approximated cross section splines are made compatible. They are required to have similar degree which is 3 here and need to be specified through identical knot vector. The common knot vector can be achieved by taking the average of the consequent knot vectors considering all the cross sections.

The control points for all cross-section curves are taken column by column and a second curves' family is fitted towards approximating these control points columns. This leads to second B-Spline curves family. The two control point vectors set forms control net for tensor surface which can be plotted. The control net and two knot vectors taken from each curve family completely define the surface. Figure 13 presents a fragment of right lung surface which is constructed using 3D points. Figure 14 presents a detailed view of lung fragment with ribs impression in lung surface. The appreciable results are obtained when cross-section contours are approximated through



B-Splines, Fig. 16 The lung surface being rendered considering cross sections

control points with third-degree B-Spline. The higher order curves look towards greater number of control points and produces curves which are prone with loops and wiggles.

Here there is no need for curve alignment. Figure 15 represents twisted surface. This does not imply any other problems, except slightly unpleasant visual effects. Figure 16 shows the lung surface being rendered considering cross sections.

Conclusion

In this entry, we have presented some of the important geometric properties of B-Spline curves. The properties worth mentioning are convex hull property and repeated points' effects. These curves find superior applications in computer-aided design industry. The computation

of B-Splines' in computational devices is also highlighted. An industry application on image processing with B-Spline curve for reconstructing the 3D surface for CT image datasets of inner organs further justifies the importance of these curves.

Esports; First-person shooter

Definitions

First-person shooter (FPS) = a genre of games where the camera is in a first-person viewpoint. Players make use of guns to eliminate targets and/or secure other objectives.

Esports = A sports competition with video games as the focus rather than traditional sports.

History of Call of Duty

As of 2016, the *Call of Duty* series as a whole has sold 250 million copies and five of the games have made the top 50 best-selling video games of all-time list (McWhertor 2016). The first title released in the first-person shooter *Call of Duty* series was *Call of Duty: Finest Hour*. *Finest Hour* was released on October 29, 2003. The series started as a Microsoft exclusive and it ran on the IW game engine. Today, one can find *Call of Duty* on any console or handheld device. Activision-Blizzard currently owns the series. From 2006 until 2014, there was a rotation every year between two different developers, Infinity Ward and Treyarch. In that time span, Infinity Ward developed the titles such as *The Big Red One*, *Modern Warfare 1–3*, and *Ghosts*. Treyarch, on the other hand, developed *World at War*, *Finest Hour*, and *Black Ops 1 & 2*. In 2014, a new company took on the mantle and developed the *Call of Duty* title for that year as well as being added to the rotation. Sledgehammer developed the game *Advanced Warfare*. The games developed since then have been Treyarch with *Black Ops 3*, Infinity Ward with *Infinite Warfare*, and Sledgehammer with *World War 2*. All titles in the series have an ESRB rating of M (ESRB 2021).

Call of Duty, being a franchise about war, is usually set in a war zone. *Call of Duty* has been set in the past as well as the future. *Call of Duty* has also brought some real-life events to the game. In the most recent game, the developers brought the

N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

invasion of Normandy into the game with a new game mode. *Call of Duty* is adapting to the current game market by creating their own battle royale mode called "Blackout." *Call of Duty* is also known for its Zombies game mode, where players are tasked with surviving against increasingly difficult waves of zombies with up to three other players.

Some similar FPS games to *Call of Duty* are *Halo*, *Battlefield*, *CSGO*, and *Rainbow Six Siege*. These games are played by people of all ages, but according to surveys 31% of *Call of Duty* players are between the ages of 25 and 34 (Knezovic 2021).

Call of Duty also has its own line of comic adaptations. The "Official Comic of Call of Duty®: Black Ops 4" is a ten-issue series introducing the iconic Specialists of the Black Ops Universe. The game also inspires a number of short films. In 2015, Activision announced the creation of a cinematic universe based on the *Call of Duty* franchise with a first film projected to be released in 2018 or 2019, and directed by Stefano Sollima. However, in an interview in 2020, Stefano Sollima stated that films were "no longer a priority for Activision" (Delaney 2020).

More importantly, however, *Call of Duty* burst into the esports scene in 2006 following the release of *Modern Warfare*. Activision-Blizzard hosts their own World Championship where the top teams compete each year. The Call of Duty League was launched in 2020, featuring the world's greatest professional players. As of 2021, the lineup of COD 2022 teams includes Atlanta FaZe, Florida Mutineers, London Royal Ravens, LA Guerrillas, LA Thieves, Minnesota Rokkr, New York Subliners, OpTic Texas, Paris Legion, Seattle Surge, and Toronto Ultra. The original 12 teams became 11 teams due to the merger between Dallas Empire and OpTic Chicago to form OpTic Texas. The most famous COD professional player is Chris "Simp" Lehr who has earned over $546,000 in *Call of Duty* tournaments despite being only 19 years old. He plays for the Atlanta FaZe team (Lionade Games 2021).

Cellular Automata
Mathematical models based on simple and local rules capable of generating complex behaviors.

Introduction

In his articles collection about Cellular Automata, specifically in the article entitled *Cellular Automata* from 1983, Wolfram (1994) introduces the subject with a reflection on the basic laws of physics relevant to everyday phenomena. Many of these laws involve complex systems, composed of numerous components, each obeying simple rules, so that the complex behavior of the studied phenomenon can be obtained. To discover and analyze the mathematical basis of complex systems, it is necessary to identify simplified mathematical systems that are capable of capturing the essence of the process, and the Cellular Automata are strong candidates in this matter.

Cellular Automata are mathematical models based on simple and local rules capable of generating complex behaviors. They were originally introduced by John von Neumann, under the name of cellular spaces, as an idealization of biological systems, with the particular aim of modeling systems capable of self-reproduction (Sarkar 2000).

In 1940, John von Neumann was involved in the planning of the first digital computers. His

goal was to obtain complex behaviors through simple rules for spatial interactions and temporal evolution. It would be a machine analogous to the human brain whose processing and memory units were not separated from each other, massively parallel and capable of self-reproduction (Chopard and Droz 1998).

Following suggestions by S. Ulam, John von Neumann proposed a discrete universe based on a two-dimensional lattice, whose cells are interconnected locally to one another. Each cell is characterized by an internal state, representing a finite state machine. Through a local rule of evolution, each cell updates its state in function of its own and the states of some neighboring cells. All cells of the lattice evolve according to the same local rule, which makes the system homogeneous, like many physical and biological systems. These cellular universes proposed by John von Neumann are now known as Cellular Automata (Chopard and Droz 1998; Kari 2005).

In the cellular automata proposed by Neumann (1966), a neighborhood formed by the four nearest neighbors (north, south, east, west) and 29 possible states for each cell was defined for each two-dimensional cell of the lattice. The theory of Cellular Automata was consolidated with the work of Burks (1970) and underwent a considerable simplification in Codd's work (1968).

Wolfram's researches (1994) became the pioneer author in the work with Cellular Automata as mathematical models for the study of the phenomenon of self- organization. He suggested the use of one-dimensional automata, each cell having as its neighbor the left and right cells and a set of two possible states.

Martin used polynomial algebra tools to deduce the characterization of uniform cellular automata (identical rules applied to each cell of the automaton) with a periodic boundary (Martin et al. 1984). A new era of research began in 1992 with the work on analytical characterization of the behavior of automata based on matrix algebra tools. The technique proposed in (Das et al. 1992) is able to characterize hybrid cellular automata (different rules applied to different cells) with periodic or zero frontiers.

Many papers had their interests focused on applications of automata to computing and biology. However, in the last decades, there is also considerable interest in the field of physics (Daniel 1994). In particular, models based on cellular automata for fluids have been developed, such as the Lattice Gas Cellular Automata (LGCA) (Frisch et al. 1986), electromagnetic models, such as Ising Spin Models, and models for diffusion phenomena (Weimar et al. 1991).

According to Wolfram (1994), physical systems that contain discrete elements and whose interactions occur locally can be modeled through the use of Cellular Automata. Although they are defined by simple local rules, automata can display complex dynamic behaviors on a wide scale. Such rules can be seen as a simplification of the microscopic dynamics, which reproduce the expected macroscopic behavior. For example, on a microscopic scale each cell can represent a particle of the system.

Several authors have been directing their lines of research for the understanding and application of Cellular Automatics. According to (Chopard and Droz 1998), some of these lines involve the use of automaton models for the simulation of physical and biological systems. The success obtained in these applications lies in the fact that Cellular Automata possess several fundamental properties of the physical world: they are massively parallel, homogeneous, and all interactions occur locally. Other physical properties such as reversibility and conservation laws can be programmed through an appropriate choice of local evolution rule.

Formal Definition

In a formal way, a Cellular Automata is a quadruple:

$$A = (L; S; N; f),$$

where L is a set of indices or cells; S is the finite set of states, that is, of the possible values that each cell can assume; $N : L \rightarrow L^k$ is the mapping that defines the neighborhood of each cell i as a collection of k cells; and $f : S^k \rightarrow S$ is the evolution function or the update rule of the automaton

(Wolfram 1994). The *f* rule is responsible for the overall dynamics of the Cellular Automaton and is applied at every instant of time in all cells. The collection of cell states at any time step is called the configuration or global state of the automaton (Chopard and Droz 1998).

Neighborhoods

An *f* update rule for an automaton is a local rule, since it only depends on the state of neighboring cells. At first there is no restriction on the size of a neighborhood. In practice, however, it is common to use only adjacent cells (Wolfram 1994). For Cellular Automata, two neighborhoods are considered: a **von Neumann Neighborhood** and **Moore's Neighborhood** (Chopard and Droz 1998).

The simplest von Neumann neighborhood consists of a central cell, which is exactly the cell to be updated by rule *f*, and its four geographic neighbors north, south, east, and west (Chopard and Droz 1998). Generalizing, (Wolfram 1994) defines the von Neumann neighborhood of radius r of cell $\mathbf{x^0}$ as:

$$N^v(\mathbf{x^0}) = \{\mathbf{x} : \|\mathbf{x} - \mathbf{x^0}\| \leq r\}, \quad (1)$$

where $\| \cdot \|$ is the norm of the sum.

For two-dimensional Cellular Automata, the definition (1) is given by:

$$N^v(x^0, x^0) = \{(x_1, x_2) : |x_1 - x_1^0| + |x_2 - x_2^0| \leq r\}. \quad (2)$$

Figure 1 shows a von Neumann neighborhood for two-dimensional automata.

In addition to the four geographic neighbors cited in the von Neumann neighborhood (north, south, east, west), Moore's neighborhood also contains the four diagonal neighbors (north-east, north-west, south-east, south-west) (Chopard and Droz 1998). Such neighborhood of radius r for cell $\mathbf{x^0}$ is defined by (Wolfram 1994) as:

$$N^v(\mathbf{x^0}) = \{\mathbf{x} : |x_i - x_i^0| \leq r, i = 1, \ldots, d\}, \quad (3)$$

where d is the space dimension and x_i is the i-th space component.

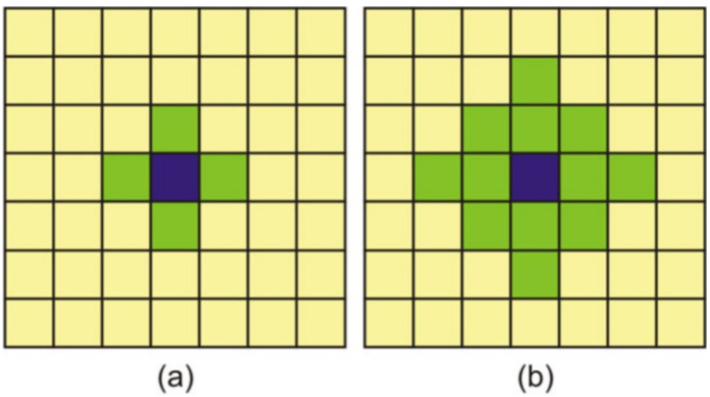
For two-dimensional automatas ($d = 2$), the definition (3) is given by:

$$N^v(x_1^0, x_2^0) = \{(x_1, x_2) : |x_1 - x_1^0| \leq r, |x_2 - x_2^0| \leq r\}. \quad (4)$$

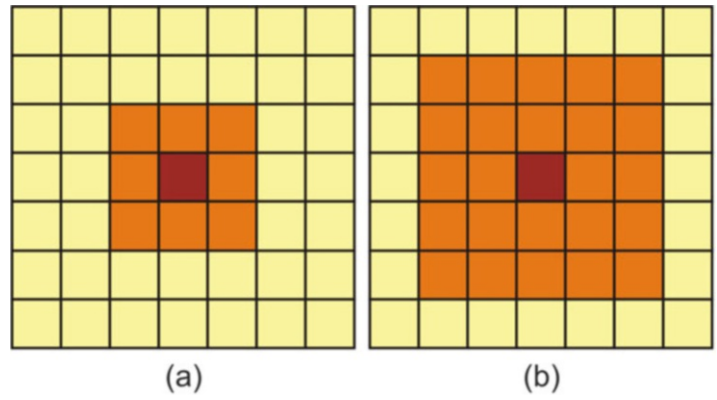
Figure 2 shows Moore's neighborhood for two-dimensional automatas.

Boundary Condition

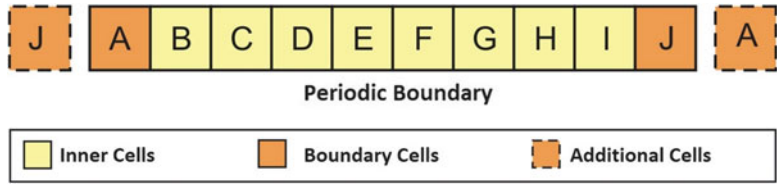
In practice it becomes impracticable to work with an infinite lattice. Once the boundaries of the lattice are defined, it is clear that the cells present at the border will not have the same neighborhood as the inner cells. It is therefore necessary to identify which cells belong to the border and apply different rules to them. Following this methodology, it is possible to define several types of



Cellular Automata Methods, Fig. 1 A von Neumann neighborhood for two-dimensional automata: (**a**) $r = 1$, (**b**) $r = 2$



Cellular Automata Methods, Fig. 2 Moore's neighborhood for two-dimensional automata: (**a**) $r = 1$, (**b**) $r = 2$



Cellular Automata Methods, Fig. 3 Periodic boundary condition for unidimensional automata

borders, each with a different behavior (Wolfram 1994). However, instead of defining distinct rules for frontier cells, another possibility is to extend the neighborhood to these cells. A widely used solution is the periodic boundary condition, which assumes that the lattice is embedded in a torus-type topology. Such a condition is obtained by extending the lattice periodically, as shown in Fig. 3. In the case of a two-dimensional automata, the periodic boundary condition assumes that the right and left sides are connected, as well as the upper and lower part of the lattice (Chopard and Droz 1998).

Other types of boundary conditions add a set of cells along the boundary, as shown in Fig. 4a–c (Chopard and Droz 1998). The fixed boundary condition defines predefined values for these new cells. The adiabatic frontier condition doubles the value of the cells that are at the border for the additional cells. The reflective boundary condition copies the value of the cell next to the border cell to the additional cell.

Choosing which type of boundary condition to use will depend on the nature of the problem being modeled. In some cases, a combination of more than one type of condition can be used, for example, in the simulation of a long channel, where one can use horizontal periodic boundary and the vertical reflective one (Chopard and Droz 1998).

Classification

A unidimensional Cellular Automata with the set of possible states defined by $S = \{0, 1\}$ and ray neighborhood $r = 1$ is called **elementary** (Kari 2005). In this configuration, there are $2^3 = 8$ possible combinations in the vicinity of a given cell, where each of these combinations can be mapped in 0 and 1. Thus, there are $2^8 = 256$ different Elementary Cellular Automata (Kari 2005). These elementary rules were studied and classified by Wolfram (1994), who introduced a methodology to name them: each of these elementary rules is specified by a sequence of eight bits,

$$f(111)f(110)f(101)f(100)f(011)f(010)$$
$$f(001)f(000),$$

where f is the automaton update rule. The bits sequence is the binary expansion of an integer in the range of $0 \ldots 255$, called **Wolfram Nomenclature** of the Cellular Automata (Wolfram 1994; Kari 2005).

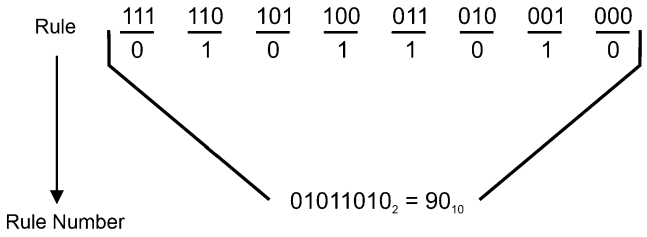
Additional Cells

Cellular Automata Methods, Fig. 4 Boundaries condition: (**a**) Fixed, (**b**) Adiabatic, and (**c**) Reflective



Cellular Automata Methods, Fig. 5 Wolfram Nomenclature

The numerical value that will identify the rule is obtained by combining the values resulting from applying the update rule f to each of the eight possible neighborhoods, thus forming a binary number. The representation of this number in the decimal base gives the numerical value for the rule (Kari 2005). For example, Fig. 5 shows the process of identifying the cellular automaton with $r = 1$, known as Rule 90.

Examples of dynamics of one-dimensional Cellular Automata are often represented in a spatiotemporal diagram. Horizontal lines are consecutive configurations, and the top line is the initial configuration. For example, Fig. 6 shows diagrams of Rule 110 on two different scales, where black represents the state 1 and white the state 0 (Kari 2005).

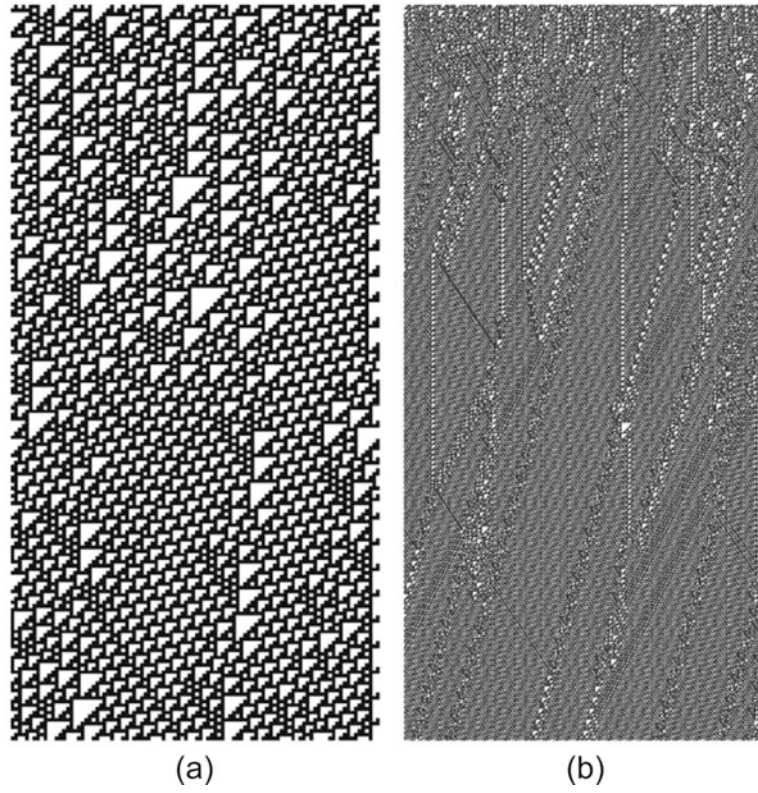
Wolfram (1994) did numerous experiments with rules of Elemental Cellular Automata using random initial configurations. Based on the types of spatial-temporal diagrams observed, he classified the rules into four categories (Chopard and Droz 1998; Kari 2005), namely:

- **Class 1**: The evolution of the automaton leads to a homogeneous state in which, for example, all cells have 0 value (Fig. 7a);
- **Class 2**: The evolution of the automaton leads to a set of stable or periodic structures, which are simple and separate (Fig. 7b);
- **Class 3**: The evolution of the automaton leads to a chaotic pattern (Fig. 7c);
- **Class 4**: The evolution of the automaton leads to complex structures (Fig. 7d).

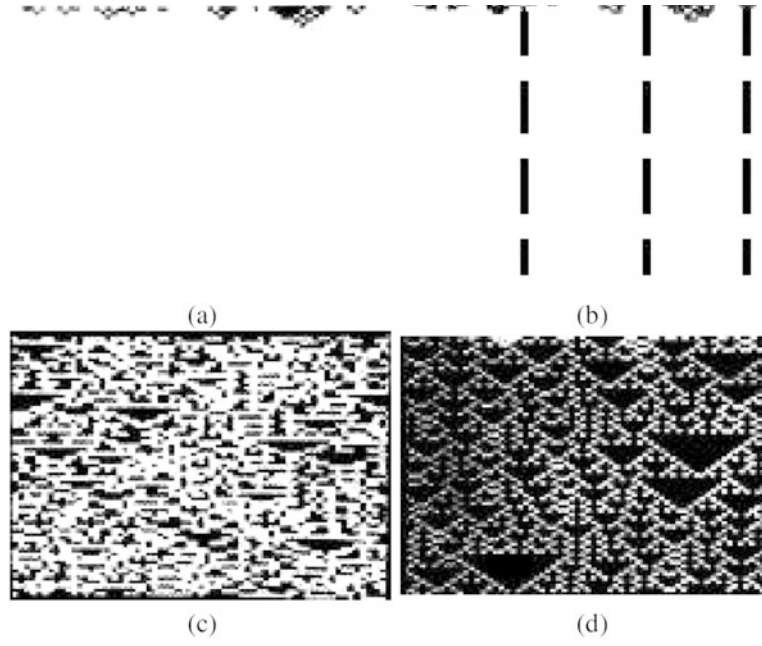
The existence of only four classes implies a considerable universality in the behavior of cellular automata. Many characteristics of a given automaton depend only on the class in which it belongs and not on the details of its evolution.

Examples of Cellular Automata

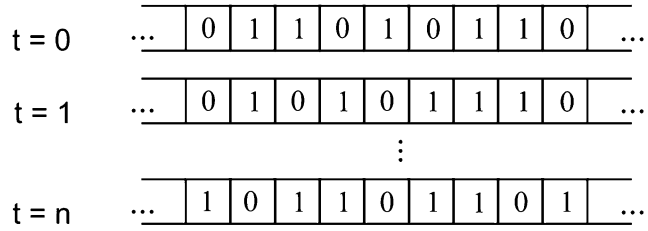
Using the traditional nomenclature (Sarkar 2000), at each time step, the collection of cell states is called the **configuration** or **global state** of



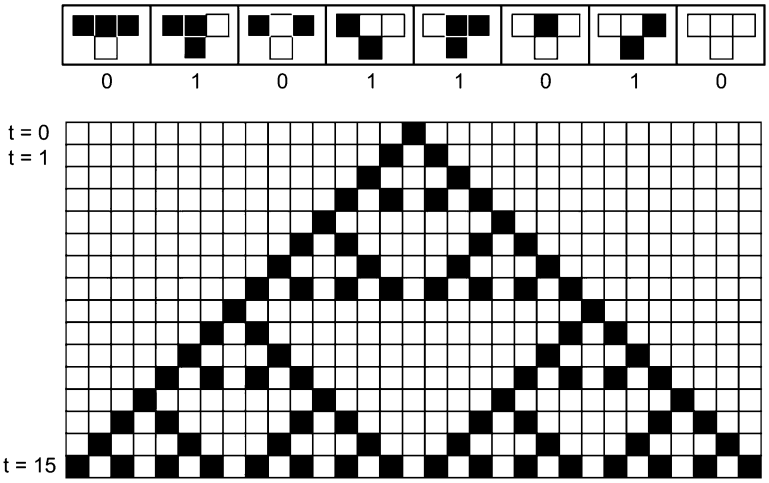
Cellular Automata Methods, Fig. 6 Space-time diagrams of Rule 110



Cellular Automata Methods, Fig. 7 Spatiotemporal diagrams: some examples of Wolfram's classification



Cellular Automata Methods, Fig. 8 Evolution of one-dimensional Cellular Automaton



Cellular Automata Methods, Fig. 9 Cellular Autamata Rule 90. Evolution after 15 time steps

the automaton. In the initial step $t = 0$, we have the initial configuration, and as time increases, the local rule is applied on all cells, as (generically) represented in Fig. 8 for one-dimensional case. Similar definitions are made for two-dimensional cases.

Rule 90

The Cellular Automata Rule 90 consists of an one-dimensional vector, whose set of possible states is formed by $S = \{0, 1\}$ and the update rule f is the binary sum of neighboring cell states (Wolfram 1994). Thus, given a cell x_i at instant t, its state a_i^t is defined by:

$$a_i^t = a_{i-1}^{t-1} \bigoplus a_{i+1}^{t-1}, \tag{5}$$

where $\bigoplus$ is the binary sum.

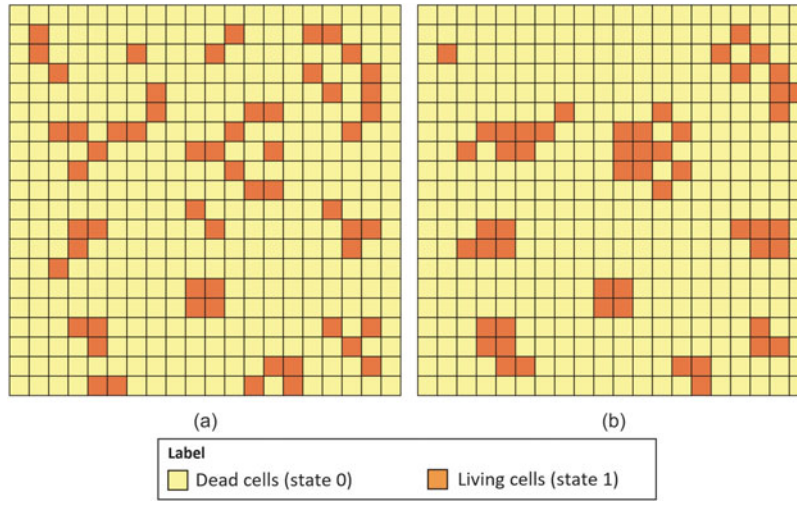
At the top of Fig. 9 we have the eight possible configurations for the neighborhood of the cell to be updated and the result of the binary sum effected. Below we can see a spatiotemporal diagram after 15 steps of evolution.

It is interesting to note that, starting from a simple initial configuration, where only one initial cell has state 1 and the others have state 0, after 15 steps already it is possible to observe the formation of a nontrivial pattern.

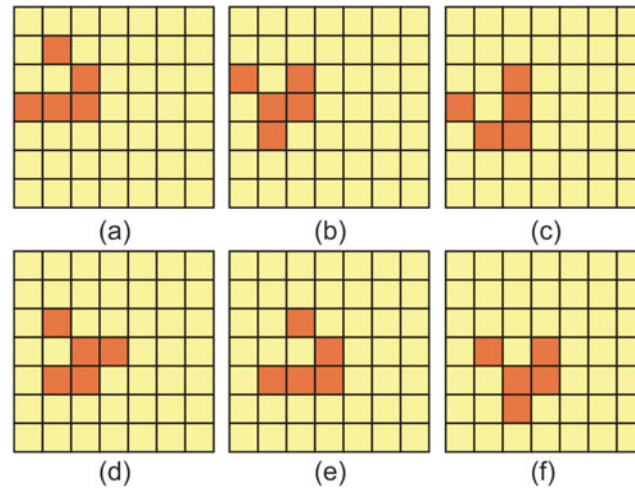
Game of Life

In 1970, the mathematician John Conway proposed the famous Game of Life (Gardner 1970). His motivation was to find a $2D$ automaton that would generate complex behaviors (Chopard and Droz 1998). The Game of Life consists of a two-dimensional lattice, where each cell can contain the 0 or 1 values. For this set of states, Conway classified the cell in vivo, if it contains the value 1, or dead, to the value 0. This automaton uses the Moore's Neighborhood (Kari 2005).

The update function f seeks to simulate an artificial life, based on the following rules:



Cellular Automata Methods, Fig. 10 Game of life: (**a**) initial step, (**b**) step 1



Cellular Automata Methods, Fig. 11 Gliders at Game of Life: (**a**) initial step, (**b**) step 1, (**c**) step 2, (**d**) step 3, (**e**) step 4, (**f**) step 5

- A cell whose state is 0 and which has exactly three living cells in its neighborhood passes to the state 1.
- A cell whose state is 1 and which contains less than two living cells in its neighborhood passes to the state 0.
- A cell whose state is 1 and which has in its vicinity more than three living cells passes to the state 0.

Figure 10 shows an example of Game of Life in a 20 × 20 lattice.

The Game of Life has a very rich behavior. During the evolution process of the automaton, it is possible to notice the emergence of complex structures, such as the so-called gliders, shown in Fig. 11. Gliders are specific cell configurations which have the property of moving around in space. We can observe in Fig. 11 that the configurations (e) and (f) are translations of configurations (a) and (b), respectively.

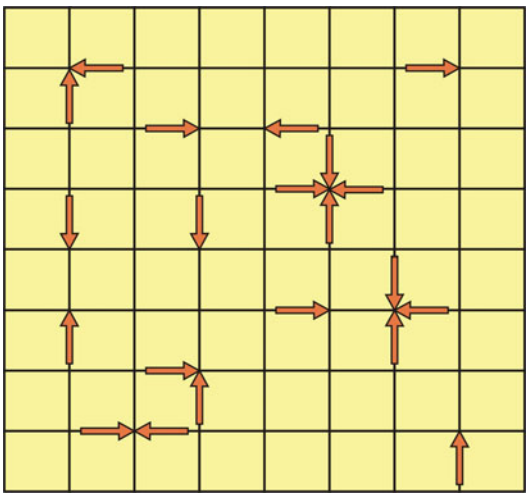
HPP Model

The HPP model is part of a group of specific Cellular Automata, called Lattice Gas. It was developed by Jean Hardy, Olivier de Pazzis, and Yves Pomeau in the 1970s. His proposal is to

model fluids via cellular automata, using simple and local rules that mimic a particle dynamics. The essential characteristics of the actual microscopic interactions that are taken into account are the laws of conservation of the linear momentum and conservation of the number of particles (Chopard and Droz 1998).

The HPP is defined in a two-dimensional lattice, and the basic idea of its dynamics is to work with particles that move along the directions of the lattice, following appropriate rules. The set of possible states is composed of $S = \{0, 1\}$ and represents the absence or presence of particles. Figure 12 shows an example of a configuration of the HPP particles.

By definition, Cellular Automata work with a finite number of bits to represent the state of each cell. Therefore, in order for the molecular dynamics of the HPP to be compatible with the automata's dynamics, there must be a restriction of the quantity of particles present simultaneously in a given cell (Chopard and Droz 1998). Such a constraint is called **Principle of Exclusion** which guarantees that, given a lattice cell, there can only be at most one particle incident in a given direction of motion, at a given instant of time. Thus, four bits of information for each cell are sufficient to describe the system during its evolution.

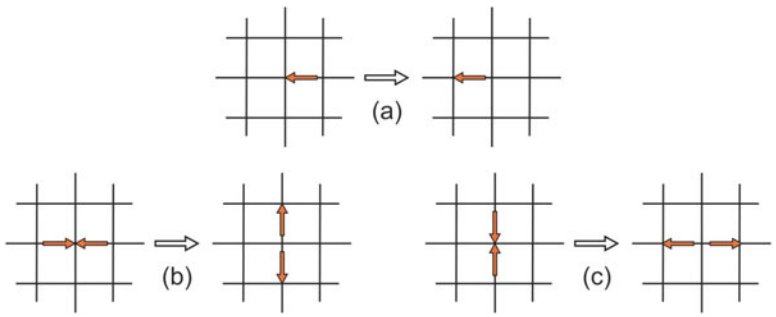


Cellular Automata Methods, Fig. 12 Particles configuration example in HPP model

The HPP update rule consists of two steps: collision and propagation (Chopard and Droz 1998). The collision phase specifies the interaction between particles entering the same lattice node. It is at this stage that the particles are "rearranged" in different directions, in order to ensure that the exclusion principle is satisfied, as shown in Fig. 13b–c. In propagation phase, each particle moves to the neighboring cell, in the direction corresponding to its direction of motion, as shown in Fig. 13a.

The purpose of the HPP rule is to reproduce certain aspects of actual interactions between particles, such as the conservation of momentum and the amount of particles. Looking for Fig. 13b–c we can observe that during the collision process a pair of particles with null moment along a given direction is transformed into another pair of particles, also with the null moment, moving on the perpendicular axis.

Another important feature in the HPP model is invariance under time reversal (reversibility). At any given moment, if the direction of movement of all particles is reversed, the system will recover



Cellular Automata Methods, Fig. 13 HPP Rules: (**a**) Propagation, (**b, c**) Collision

its entire history. This property becomes a limiter when the intention is to use the model to describe a real fluid, since in this case there is the presence of viscosity. Other limitations are related to algebraic invariants of the adopted lattice (Wolfram 1994).

Challenge-Based Learning in a Serious Global Game

David Gibson[1], Leah Irving[2] and Katy Scott[1]
[1]Curtin University, Perth, WA, Australia
[2]Charles Sturt University, Wagga Wagga, NSW, Australia

Synonyms

Collaborative problem solving; Contextual learning and teaching; Learning challenges; Open-ended problem-based learning; Project-based learning

Definition

Challenge-based learning offers a call to action that inherently requires learners to make something happen. In a serious game context

learners often work in teams in a digital game-based platform to research their topic, brainstorm strategies and solutions that are both credible and realistic in light of time and resources, and then develop and execute a solution that addresses the challenge in ways both they themselves and others can see and measure. Teams often compete with each other for high scoring solutions, recognition, and rewards. For example, a business might offer an "X-Prize" for a solution needed for driverless cars. Challenge-based learning can thus be seen as a way to incentivize crowd-sourced ideation and solutions.

Introduction

The term challenge-based learning arose in the USA early in the twenty-first century with the support of innovative technology groups such as Apple Education, the New Media Consortium, The Society for Information Technology and Teacher Education, and the US Department of Education Office of Educational Technology. Unique applications supporting challenge-based learning in higher education are now arising, supported by a cloud-based mobile technology platform that can be used for bridging informal to formal learning, recruiting students into university, reaching larger numbers of people with game-based approaches, envisioning student engagement in work-integrated learning, and assisting students to acquire evidence of attainment of graduate capabilities such as leadership, critical thinking, creativity, communication skills, and experience in international team collaboration (Gibson et al. forthcoming, 2018a, b).

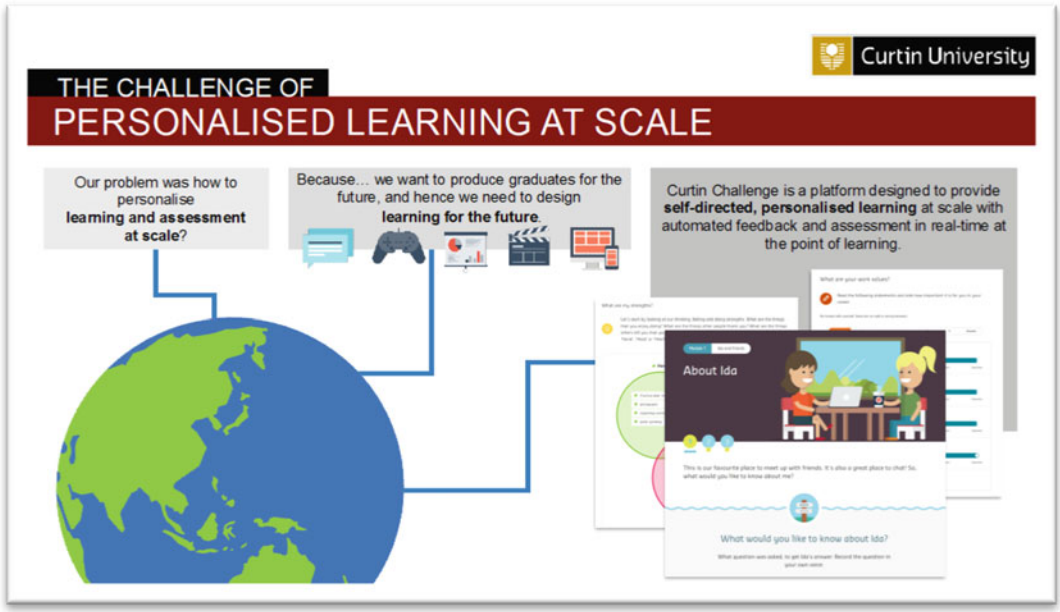
State of the Art Work

Challenge-based learning is a teaching model that incorporates aspects of collaborative problem-based learning, project-based learning, and contextual teaching and learning while focusing on current real-world problems (Johnson et al. 2009). In particular, online global learning challenges engage students' curiosity and desire to learn by making central the solving of open-ended problems as a member of a self-organizing and self-directing international team (Harris and Nolte 2007). When delivered as a mobile learning experience, challenges can integrate twenty-first-century tools, require collaboration, and assist students in managing their time and work schedules, while effectively scaling to large numbers of students. Set in the environment of a friendly serious game competition where people experience elements such as automated feedback, points, leader boards, badges, and leveling up for rewards, challenge-based learning increases motivation toward high performance (Gibson and Grasso 2007). Research on challenge-based learning is beginning to show impacts such as increased engagement, increased time working on tasks, creative application of technology, and increased satisfaction with learning (Johnson et al. forthcoming, 2018; Roselli and Brophy 2006).

Similar to problem-based and project-based learning, and borrowing liberally from those well-established approaches (see Gibson et al. 2011) and the Buck Institute for Education (www.bie.org), the additional structure of global relevance, international collaboration, and team-based competition leads to a unique objective, expressed well in a recent report by the New Media Consortium (Johnson et al. 2009).

Design and Implementation Roles

The design method for the future of challenge-based digital learning experiences is a team-based effort of people knowledgeable in subject matter, dramatic narrative, mechanics of game-like interactions and rewards, digital-media artists and communicators, and computational science tools for algorithms and visualizations (Gibson et al. 2007). The mission of such interdisciplinary teams when creating challenge-based learning experiences is to create a symbolic space for transmedia narrative (Passalacqua and Pianzola 2011) to be introduced as well as to evolve through the participatory culture (Jenkins et al. 2006) shared by those who take up the challenge.



Curtin University
THE CHALLENGE OF
PERSONALISED LEARNING AT SCALE
Our problem was how to personalise learning and assessment at scale?
Because... we want to produce graduates for the future, and hence we need to design learning for the future.
Curtin Challenge is a platform designed to provide self-directed, personalised learning at scale with automated feedback and assessment in real-time at the point of learning.
About Ida
What would you like to know about Ida?

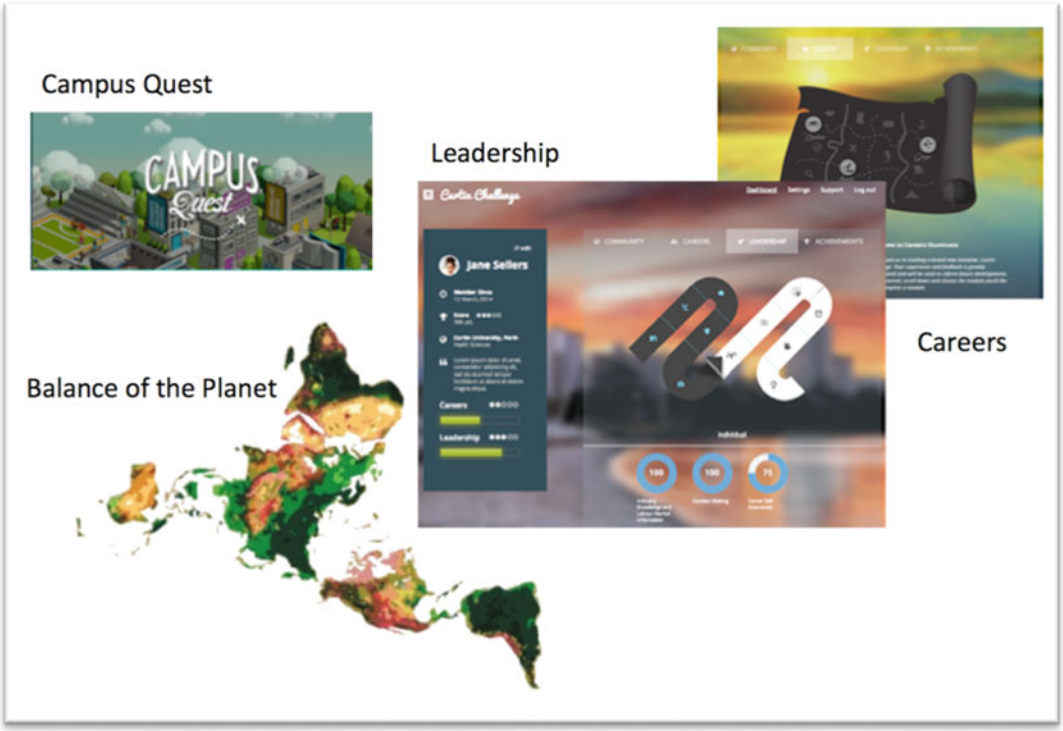
Challenge-Based Learning in a Serious Global Game, Fig. 1 Curtin Challenge platform as a solution to personalizing learning at scale

Instructors have a special role in constructing a problem space with key ideas, essential questions, resources, and evaluation criteria. In the challenge-based learning framework, instructors are designers of the digital-learning experience who put in most of their time in up front and then take a backseat during the implementation while individuals and teams are learning, working, communicating, creating, and submitting artifacts. Subject matter experts (SMEs) in a discipline work with a digital-media team and game-creation team to engineer the learning experience. Most of the input from subject-matter-expert authors is gathered during the design phase and is embedded into the digital experience through public scoring rubrics, artifact descriptions for final submission, and scaffolding activities, which the team members can choose to experience or ignore. A new structure of teaching, created via collaborations among SMEs working with learning-experience designers and technical teams, is arising as an innovation to create new structures of teaching and learning in response to the myriad changes taking place in higher education today (Grummon 2010).

Show Case

At Curtin University, in Perth Australia, a "Challenge platform" online toolkit has been developed to assist with authoring and delivering challenge-based individual and team learning at scale (Fig. 1). The platform can be compared to a game-engine marketplace with a common API for learning outcomes across the various learning experiences. Individual challenges include learning about oneself as a leader or exploring a career and team challenges available in "Balance of the Planet" including solving one or more of the UN Sustainable Development Goals (Fig. 2).

The platform roadmap includes features that support individual- and team-based learning in a serious game context:



Challenge-Based Learning in a Serious Global Game, Fig. 2 Individual and team-based challenges provide a serious game context for learning

- Self-organizing teams
- Self-determined paths of action
- Transparent milestones for seeing progress
- Self-scoring and peer scoring of artifacts
- Expert scoring for awards and recognition
- Openness to external mentors and advisors helping solve problems
- Automated feedback on progress
- 24-7 access
- Support tools for chatting, coproduction, and automated messaging
- Administrative dashboard for research data and monitoring

Challenges Facing the Arab Animation Cinema

Tariq Alrimawi
Graphic Design Department, University of Petra, Amman, Jordan

Synonyms

Arab animation; Arab cinema; Arab filmmakers; Muslim filmmakers; Political communication; Visual culture

Definition

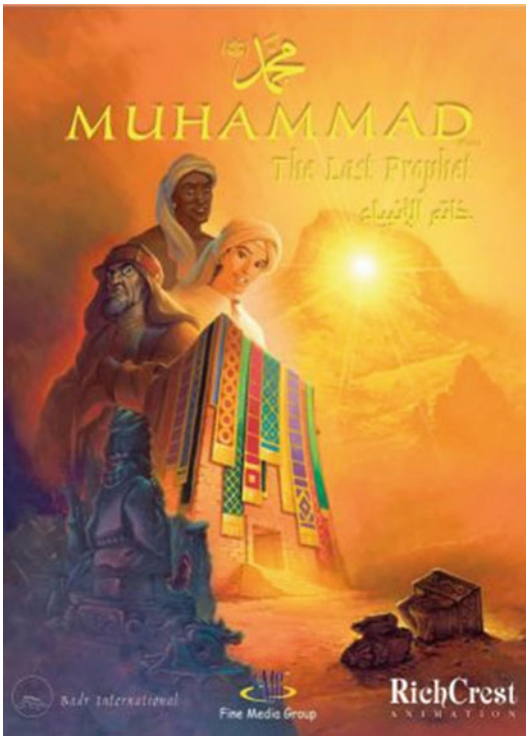
Arab filmmakers attempt to export their animated films to an international market and try to speak to other global cultures. They seek to build a bridge between the Arab world and the West through animated films which have been adapted from Arab and Islamic sources, but speak to the universal human condition. The relationship between Islam and the West, though, remains very complicated; the West looks at these projects and already has a perspective about them as religious and ideological propaganda, especially after 9/11, 2001. Thus, the majority of these Arabic animated films are rejected by the West because of concerns that these films represent the unwelcome principles of foreign cultures. Inherently, there is an Islamophobia about Islamic cultural products as soon as they come to the West; there is suspicion of them and extensive interrogation of them. Ironically, when Western artifacts are exported to Arab countries, though almost inherently at odds with Muslim ideology and Muslim politics, they sometimes find distribution and audiences. The consequences of this relationship between Arab countries and the West is not only ideological, however, and also concerned with the fact that Arab filmmakers and producers face economic challenges, and a number of Arab animation studios went out of business or stopped making more feature animated films due to the difficulties of reaching international marketplaces. Thus, the focus of contemporary Arab animation is mostly low-budget projects distributed through YouTube and social media, which became the main platform for Arab animation artists to distribute their political works during the "Arab Spring" in Tunisia, Egypt, Libya, Yemen, Syria, and elsewhere in the Middle East since 2011.

Introduction

After 9/11, Arab animation producers struggle to screen their films at cinemas in Europe and the USA. The irrational fear of Arabs and the Islamic religion [has] increased in the West, and Muslims have become targets of increased hostility, creating the now so-called Islamophobia. (Kalin 2011). The first use in print of the term Islamophobia was in the report of the Commission on British Muslims and Islamophobia in 1997 (Iqbal 2010). This

commission was established in 1996 by the Runnymede Trust, an independent research and social policy agency. The report was called *Islamophobia: A Challenge for Us All* and describes the main features of Islamophobia and the challenge it poses to Muslim communities. It covers central topics about Muslim communities and concerns in Britain, media coverage, violence, and building bridges by intercommunity projects and dialogue. The report also contains many subtopics separately from the main text, such as diversity and difference within Islam, perception of Islam as a threat, opposition to immigration, and other topics. Moreover, the report shows statistical tables of Muslim issues such as residential patterns, employment and unemployment, population in some cities in Britain, and incidents seen as racially motivated. The commission distributed more than 3,500 copies to government departments, organizations, social communities, universities, and the media.

The report defined the term Islamophobia as "the practical consequences to such hostility in unfair discrimination against Muslims individual and communities, and to the exclusion of Muslims from mainstream political and social affairs" (Runneymede Trust 1997). Islamophobia has affected Muslim film producers' capacity to show their Arab/Islamic animated films to a Western audience. For example, a Saudi film production company called Badr International invested around 12 million US dollars, which is the highest budget for any Arabic animated film so far, in their first feature animated film, *Muhammad the Last Prophet* (2002) (Jammal 2012). These movies were made by a team of artists from Hollywood who combined traditional hand drawing with computer graphics and effects. The director who had the unique experience and challenge of making this movie was Richard Rich, who worked for Disney for many years. The soundtrack was composed by Emmy-award winning composer William Kidd. In consequence, the movie was described as being an "(old-fashion) Western-style entertainment about a distinctly non-Western subject" (Stevens 2004). However, this movie was the first feature-length animated film that focused on the biography of the prophet



Challenges Facing the Arab Animation Cinema, Fig. 1 *Muhammad: The Last Prophet* (2002) (Directed by Richard Rich)

Muhammad and the journey with his followers from Mecca to Madina, set around 1400 years ago during the early years of Islam (Fig. 1).

There were two versions released of the feature and the short films, one in the Arabic language and one dubbed in English hoping to gain the attention of non–Arabic speaking audience. Badr made an agreement with many companies and cinemas to distribute and screen the film *Muhammad the Last Prophet* in the USA. However, the film's production finished at around the same time of 9/11 in 2001. The consequence was that most of the agreements were cancelled by US cinemas and distributors due to Islamophobia. Badr held the film for 2 years without screening it in cinemas. They did not want to sell the film's DVD to the market before the theatrical release. Later, a new Arabic distribution company based in the USA called FineMedia arranged a theatrical release in 37 US cities with Eid al-Fitr in 2004. The venture was not successful and revenues were very small.

Therefore, Badr International stopped making any more animated films and went out of business in animation field.

Limited Resources and Release

The bibliography related to animation in the Arab world is very limited, and it was hard to find published materials related directly to the subject; only two published references relating to Arab animation were found: the first one being *Cartoons: One Hundred Years of Cinema Animation* by Giannalberto Bendazzi (1994) and the second, the booklet *Animation in the Arab World, A glance on the Arabian animated films since 1936* by Mohamed Ghazala (2011).

Bendazzi's book covers the history of animated films assessing over 3,000 films in more than 70 countries worldwide. Nevertheless, the book covers only 3 of 22 Arab countries and contains only small animated productions from Egypt, Tunisia, and Algeria. Most of those Arab animation productions were TV series and TV commercials, and a few made as short films. An electronic communication was arranged with Bendazzi (2012) to ask what the reasons were for having such a small selection of Arab animation in his book (Bendazzi 2012). Bendazzi's first sentence was "I think you will be disappointed by my answers"; this sentence immediately gives a negative impression about Arab animation cinema and the challenges it faces.

Bendazzi points out that when he was writing the book, from 1983 to 1988, it was hard to find Arab animated films due to the lack of connections at that time such as internet, e-mails, and social network websites. In addition, Bendazzi faced language difficulties communicating with Arab film historians and filmmakers. Moreover, Arab critics did not pay attention to animation films.

In contrast to all the challenges that face Arab animation, and the small number of animation productions compared with the Western animation productions, the Arab world is abundant with magnificent folktales such as the *One Thousand and One Nights* stories which are suitable for adaptation to make into many animated films. From the inspiration of the *Arabian Nights* stories Western film producers have developed animated films such as *The Adventures of Princes Achmed* (1925), *Aladdin* (1992), and *Azur and Asmar* (2006). Arabs, however, have not used their own past Arabian stories to reach either the domestic and international animation marketplaces. Bendazzi recalls:

> Arab animators should participate to the great international festivals; watch the masterpieces of ten, twenty, seventy years ago, and read translated books. They first must be great animators with a distinctive style, and only then adapt any text from any literature. (Bendazzi 2012)

The Arab animation industry needs people with strong skills in animation techniques and process such as character design, animation, editing, lighting, compositing, sound, music, and marketing, and then start thinking about making successful animation feature films to screen to the Arab audience and then export these films to the international audience. However, one of most important parts of any successful film in the contemporary era is the story; the film would be good as soon as the story is good. Also, quality could come in different method and ways; it does not have to imitate Disney and Pixar styles. The Arab filmmakers should think of using contemporary tools and creating fresh and unique styles such as the Iranian animated films *Persepolis (2007)* and the documentary *The Green Wave* (2011). Thus, the Arab filmmaker should focus more on making universal stories with different styles in order to show them to audiences all around the world.

In March 2012, an invitation has been received from the *Cairo International Film Festival for Children (CIFFC)* to present my short animated film *Missing*. The CIFFC, organized by the Ministry of Culture in Egypt, is one of the biggest children's film festivals in the Arab region. There were more than 100 short and long feature live-actions, documentaries, and animated films at the official competition. Most of them were international productions and few were from Arab filmmakers, and there were no Arabic feature length animated films. This shows the limited amount of animated short and feature film productions in Arab countries.

During the festival, an interview was arranged with one of the festival's jury committee, Dr. Mohamed Ghazala (2012), the author of *Animation in the Arab World*: *A Glance on the Arabian Animated Films Since 1936*, the sole booklet on the market about Arab animation history. Ghazala is also the founder and director of the regional African and Arabian chapter of the *International Association of Animation Filmmakers* (ASIFA). The aim of this organization is to involve Arabic and African animation filmmakers in creating, developing, and promoting their own regional identity and having an impact in the international animation market by participating in festivals and setting up some animation workshops.

Ghazala notes that the booklet is a collection of five articles about Arab animation published in a South Korean animation magazine called *Animatoon* in the Korean language. Every two months, he covered the animation in different areas of the Arab world such as Egypt, North Africa, the Ash-sham area, and the Gulf area. Subsequently, he collected the five articles with some editing then presented them as a conference paper at *Athens Animfest Animation Festival* in 2011 in Greece. The booklet contains only 56 pages and includes a small filmography of Arab animation with some valuable data that is important to any researcher interested in Arab animation.

Ghazala explains the reasons behind the small selection of Arab animation in his booklet; he collected those Arab animated films individually by himself. The main problem was that he could not find any official archive or library for Arab animation. It was hard to find the original copy of the animated films, and few Arab animated films are available on the internet, and then, only with low resolution. Ghazala points out the problems of Arab animation films in terms of quantity and quality compared with the Western animation productions:

> I have attended many international animation festivals as a filmmaker or jury member; unfortunately, there were hardly any Arab animation in those international festivals. There is no systematic approach to producing and educating animation in the Arab region, most of the experiments that happened by the Arab animation filmmakers to show their Arabic identity and culture through animation are independent and without serious support from the Arab governments. Most of the high quality animation productions in Arab countries such as Egypt, Jordan, Tunisia and Morocco focus on TV commercials and TV series especially for Ramadan, and don't have interest in producing artistic films for cinema and festivals. You can only see the graduation projects by the Arab art students, who make artistic animation films, then after the graduation, they work in the industry to produce commercial works and the artistic work is disappearing quickly. (Ghazala 2012)

Arab film productions focus more on making live-action films. For example, in Egypt, "The Arab Hollywood," there had been produced thousands of live-action films (Shafik 2007). Surprisingly, Al Sahar Studio, one of the biggest animation studios in Egypt, has had financial difficulties since 1998 in attempting to complete their first Egyptian feature length animated film *The Knight and the Princess* (Ghazala 2011). Therefore, it is appropriate to question the reasons why there have been so few animated feature films successfully produced in the Arab world; Is it because the Arab film producers think that animation is only for television and children? Ghazala points out that for a long time, Arab national television has imported all the animation films and TV series that suited children:

> When I was a kid I thought that the animation is only *Walt Disney's* productions. When I grew up, a friend gave me a video tape of animated films produced in the Czech Republic, which has completely different style than the films we used to watch in our national televisions. These Czech animated films were abstract, artistic and nice stories. In that time I realized that animation could be for kids and adults. The Arab did not screen the East European animated films that were produced in the 60s and the 70s in the cinemas and television; these films could inspire the Arab of making such artistic animation films. (Ghazala 2012)

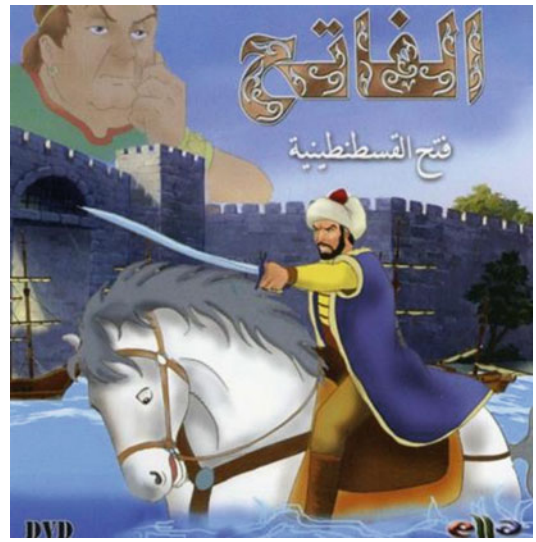
Another challenge facing Arab animation is the lack of animation academies in the Arab region; many universities have Arts schools that focus on graphic design and the fine arts, but only a very few schools teach animation. In addition, there are a few animation festivals in some Arab counties

such as the Cairo Children's Film Festival in Egypt, the Meknes International Festival for Animation Films in Morocco, and the newly established festival JoAnimate in Jordan. In contrast, the governments of Europe, Japan, and North America acknowledge the importance of the animation industry by giving financial support and arranging many animation festivals which develop the filmmakers and the animation industry in their countries.

Making animated feature films in the region is a massive risk due to the unstable market and the high expenses of making them. On the other hand, the Arab countries include more than 300 million people who speak the same language and share the same culture, and this would clearly be a promising marketplace if there were appropriate methods for media marketing to reach it. The Arab producers should take the Western animation markets as a model, and see how animation could have huge success and profits at the box office.

In 2009, Aljazeera News, one the biggest news broadcasting channels in the Middle East, had an interview with the animation producer and the cofounder of Ella Cartoon Studios, Mr. Osama Khalifa from Saudi Arabia. The title of this interview was *The reasons for the weaknesses of the Arab animation industry* (Without borders [Bila Hodoud] 2009). Khalifa produced more than 14 Arabic animated feature-length films; started with the feature animated film *The Island of the light* (1988) which was based on the Arabian novel *Hay Bin Yakzan* (*Living son of Awake*) which was written by the Andalusian philosopher and novelist Ibn Tufail in the early twelfth century.

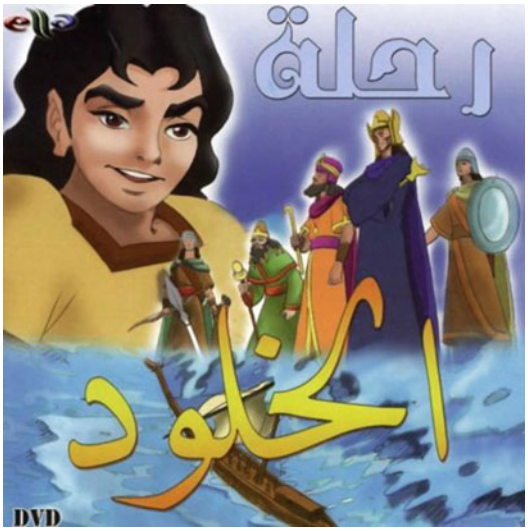
Most of Ella Cartoon Studios films are historical, such as *The Conqueror* (*Al Fatih,* 1995), a feature animated film that tells a story about the conquer of Constantinople in the fifteenth century by the Turkish leader Sultan Mehmed Al Fatih (Fig. 2). Also, the animated film *Conquered Andalucia* (*Fateh Al Andalous,* 1998), which tells a story about the Muslim hero Tariq Ben Ziad when he conquered Andalucia in Spain in the early eighth century to spread the religion of Islam in the West. The studio also made the



Challenges Facing the Arab Animation Cinema, Fig. 2 *The Conqueror* (1993) (Produced by Osama Khalifa)

feature animated film *The Lion of Ain Jalout* (*Asad Ain Jalout,* 1998) which tells a story about the Egyptian Muslim leader Prince Saif Al-din Qutuz when he led the Muslims to achieve victories against the Crusaders in Mansoura in Egypt and Mangouls in Ain Jalout in Palestine in the thirteenth century.

However, Khalifa also produced some religious animated feature films such as *The Immortal Journey* (*Rehlat Al-kholoud,* 1996) directed by Darwish Yasin (Fig. 3). The story is adapted from the Holy Quran, Surat Al-Buruj (The Mansions of the Stars) Chapter 85 verses 4–9. All of the animation and illustrations were made in cooperation with a studio in Turkey. However, the style of the illustrations and animation is similar to the Japanese cartoon visual style used in Anime and Manga, using common visual elements such as big eyes, minimum facial details, a lot of light and shade, and numerous camera rotations. Khalifa also produced a number of political animated films especially about the Palestinian Israeli conflicts, such as *The Olive's Dream* (*Holm Al Zaytoun*, 2009) and a 3D animated film *Martyr of World* (*Shaheed Al-alam*, 2003).



Challenges Facing the Arab Animation Cinema, Fig. 3 *The Immortal Journey* (1994) (directed by: Darwish Yasin, produced by Osama Khalifa)

None of the above films were supported by the Arab governments; they were made using their own money only. Khalifa indicates that the Arabic media market was empty of animation film productions and he decided to take a risk and make Arabic animated films for the Arab and international audiences. However, most of his animated films have been made using high quality overseas production in Turkey, Ukraine, and China due to the lack of Arab animation artists. Khalifa noted that the Arab animation industry produces less than 0.5 % of Western animation production. One year after the *Without Borders* interview, Ella Cartoon Studio went out of business, after 30 years of animation production.

Conclusion

Arab film producers made number of animated films by using a variety of stories such as religious, historical, political, and folk tales. In addition, the target audiences of most of his films are the general public and families. Nevertheless, they did not make enough profit for the studio to keep producing Arabic animated films. For this reason, his production company stopped making more films. The evidence suggests that there are a number of reasons for this struggle domestically and internationally, such as *cultural challenges*; the majority of the Arab people think that animation films are only for children and for that reason there is no success for theatrical releases of any Arabic animated films so far. However, Arab animation filmmakers are trying to convince investors and Arab audiences that the target audience of their animated films is general and refer to the huge success in animation in the West. Another reason could be *political challenges*; some of the films were made about the Palestinian Israeli conflict and those films could be difficult to screen in Europe and USA, because they might be considered as anti-Semitic. Moreover, most of Arab films have Muslim heroes who achieved victories against the Crusaders and Byzantine empires. The Arab film producers want to demonstrate the importance of making animated films appropriate to the Islamic religion and Muslim civilization. However, there is view that by making such historical stories, especially the conflicts between Muslims and Crusaders, would remind both Muslims and non-Muslims about the past, and it would "illustrate feelings, fears and animosities in the present" (Runneymede Trust 1997). Therefore, the target audience for any historical and religious films that show conflict with others might be limited to Muslim audiences only, and these types of animated films would be difficult to screen for an international audience due to subject matter that might offend the Western audience. This is the same as when Arabs and Muslims are offended by Western animated films that stereotype the image of Arabs and Islam in a negative manner.

Most of the Arab animated films were discussed so far are political, historical, and religious which could be one of the main reasons why those films are not reaching the international film marketplace. The previous examples show that the Arab animation industry is struggling in terms of budget, marketing, broadcasting, distribution, and government support. However, reaching the international market could be

achievable if Arab animation filmmakers and producers make universal stories that are suitable to everyone in the world. It is worth mentioning that a number of animated films from Arab countries found that the best way of making low-budget animated films/clips was to distribute them for free via the Internet and social media such as YouTube, Vimeo, Facebook, and other social media networks. The number of Arabic online videos increased greatly during and after the recent Arab revolution, the "Arab Spring" in 2011. This recent revolution gave Arab artists the freedom of expression to discuss whatever subjects they wanted to, including the political issues which attract a large number of audiences and received international channels' attention such as CNN, France 24, ABC News, Aljazeera, and other international channels, during the Arab Spring.

Synonyms

Animation scripting; Scripting environment; Scripting language

Definition

Scripting languages for character animation can be characterized as the earliest type of motion

control systems. In scripting environments, the required animations are generated by writing a script in the animation language. This means that a user must learn the animation scripting language. Such systems typically allow scenes and objects to be described, along with their relationship with each other. Among other advantages, they require no user interface and can therefore be implemented as cross-platform solutions.

Introduction

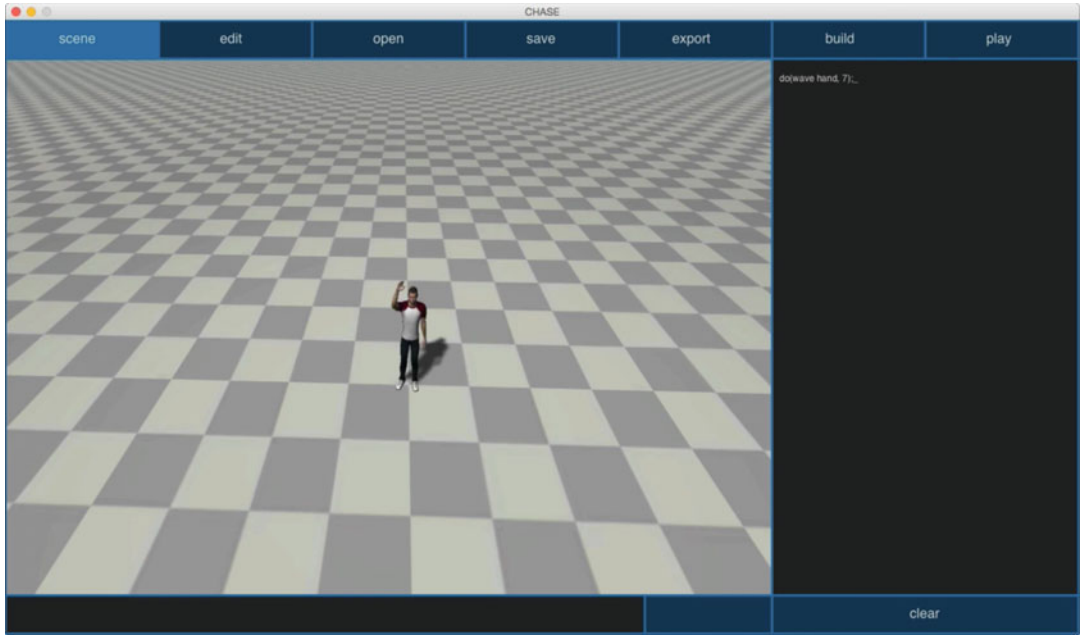
Character animation can be characterized as a complex and time-consuming process. This is especially true when animating virtual characters based on key-frame techniques, as this requires prior knowledge of software solutions. Moreover, artistic skills are also required since the virtual character should animate as naturally as possible.

In order to avoid time-consuming processes in animating virtual characters, motion capture technologies now provide high-quality and realistic animated sequences. This is possible because the ability to capture real humans in the act of performing is achieved through the provided required motions. The advantages of motion capture techniques are numerous, especially in the entertainment industry. However, the captured motion data, itself, is not always usable, since virtual characters should be able to perform tasks in which the required constraints are not always fulfilled. Thus, methodologies that retarget (Gleicher et al. 1998), wrap (Witkin et al. 1995), blend (Kovar et al. 2003; Park et al. 2002), splice (Van Basten and Egges 2012), interpolate (Kovar et al. 2002; Mukai and Kuriyama 2005), etc., the motion data have become available to help the animators to create the required motion sequences. In addition to the motion synthesis techniques that are based on software solutions, animating a virtual character through programming is also difficult. This is especially true in cases where animators, artists, and students do not have the required programming skills. Hence, animating virtual characters in order to visualize ideas and generate simple scenarios in which virtual characters evolve can be a very complex process.

Based on the aforementioned difficulties that inexperienced programmers can face, this paper introduces a simple, easy-to-use, scripting environment for animating virtual characters, which is based on a small number of scripting commands. The scripting environment presented (see Fig. 1), which is called CHASE, provides a user with the ability to script the action of a character as well as to script possible interaction between a character and objects that are located within the virtual environment.

In order to implement CHASE, the following parts were developed. Firstly, identify the basic actions that a character should be able to perform and also generate the basic scripting commands. Secondly, a number of parameters that should allow the user not only to synthesize the required motion of a character but also to gain a higher level of control of each action of the character were defined. By using a reach number of motions that a character can perform, as well as by associating these actions with specified keywords, a motion dataset is created. The input commands are handled by a number of developed background algorithms, which are responsible for retrieving the desired motions and synthesizing the requested actions of the character. During the application's runtime, CHASE synthesizes the requested motion of the character and displays the final animated sequence.

The remainder of this paper is organized as follows. The section "Related Work" covers related work in character animation by presenting previous solutions for animating virtual characters that are based on interactive or automatic techniques. Previously developed scripting environments for the animation of virtual characters are also presented and discussed. A system overview of CHASE is presented in section "System Overview." The script commands, possible parameters, and additional functionalities that have been developed for CHASE are presented in section "Scripting Character Animation." Finally, conclusions are drawn and potential future work is discussed in section "Conclusions and Future Work."



Character Animation Scripting Environment, Fig. 1 The interface of CHASE

Related Work

This section presents work that is related to the solution presented. Specifically, the following paragraphs present methodologies that use different input devices or easily specified constraints for animating virtual characters, systems that provides to a user the ability to synthesize task-based or scenario-related animated sequences, and previously proposed scripting environments for character animation. Finally, the advantages provided by CHASE comparing by previous solutions are presented.

Interactive character control can be classified according to the input device that is used for the character animation process (Sarris and Strintzis 2003). In general, the character controller can be a standard input device, such as a keyboard and a joystick (McCann et al. 2007). Alternatively, it can be more specialized, such as text input (Oshita 2010), prosodic features of speech (Levine et al. 2009), drag and drop systems where the motion sequences are placed into a time-line (Oshita 2008), sketch-based interfaces (Davis et al. 2003), or the body of a user (Chai and Hodgins 2005), while the motion is captured by motion capture technologies. Each of the previously mentioned methodologies has advantages and disadvantages. The choice of the most appropriate input device depends on the actual control of the character's motion that the user requires.

A variety of methodologies for the animation of a virtual character based on easily specified constraints have also been examined. These solutions are based on motion graphs (Kovar et al. 2002); literature such as Safonova and Hodgins (2007); simple footprints (Van De Panne 1997) that a character should follow, on space-time constraints as proposed in Cohen (1992); or statistical models (Min et al. 2012) that are responsible for retrieving and synthesizing a character's motion. However, even if easily specified constraints enable a user to animate a character, different frameworks that permit either the interactive or automatic animation of a character have been developed. In Feng et al. (2012), which is a task-based character animation system, by using a number of screen buttons, the user is able to animate a character and make it interact with objects that are located within the virtual

environment. Other methods (Thiebaux et al. 2008; Kapadia et al. 2011; Shoulson et al. 2013), which can be characterized as scenario-based character animation systems, provide automatic synthesizing of a character's motion based on AI techniques.

In the past, researchers developed scripting languages and systems in the field of embodied conversational agents. The XSAMPL3D (Vitzthum et al. 2012), AniLan (Formella et al. 1996), AnimalScript (Rößling and Freisleben 2001), SMIL-Agent (Balci et al. 2007), and many others enable a user to script a character's actions based only on predefined command. Among the best known markup languages for scripting the animation of virtual characters are the Multimodal Presentation Markup Language (Prendinger et al. 2004), the Character Markup Language (Arafa et al. 2003), the Multimodal Utterance Representation Markup Language (Kranstedt et al. 2002), the Avatar Markup Language (Kshirsagar et al. 2002), the Rich Representation Language (Piwek et al. 2002), the Behavior Markup Language (Vilhjalmsson et al. 2007), and the Player Markup Language (Jung et al. 2008), which were developed for controlling the behavior of virtual characters.

The representation of all previously mentioned languages is based to an XML-style format that allows users to script tasks featuring virtual characters. However, these languages focus more on communicative behavior such as gestures, facial expression, gaze, and speech of virtual reality characters, instead of providing functional characters that can generate scenario-related animated sequences.

Various solutions that are similar to the presented methodology were proposed previously for the animation of virtual characters based on scripting commands. StoryBoard (Gervautz et al. 1994) provides the ability to integrate a scripting language into an interactive character animation framework. Improv (Perlin et al. 1996), another framework with which to create real-time behavior-based animated actors, enables a user to script the specific action of a character based on simple behavior commands. STEP (Huang et al. 2002) framework provides a user the ability to script such actions as gestures and postures. This methodology, which is based on the formal semantics of dynamic logic, provides a solid semantic foundation that enriches the number of actions that a character can perform.

The majority of previously developed scripting environments and markup languages provide only specific actions that a character can perform. An additional limitation is the inability of such systems to enhance a character's synthesized motion. Therefore, a user always receives a lower level of control of the synthesized motion of a character. Moreover, in cases in which a user must generate an animated sequence where many characters will take part, a great deal of effort will be required due to the difficulty of scripting multiple actions for multiple characters. This is especially true for users who wish to generate a sequence with animated characters, but are inexperienced in programming.

These difficulties are overcome in the presented scripting environment. Firstly, instead of enabling a user to script an animated character based on XML-related formats, a simplified scripting environment with its associated scripted language, which is based only on three commands, is introduced. Secondly, since a character should be able to perform concurrent actions, a simple extension of the basic command handles this. Therefore, the user achieves a higher level of control of a character's action. Moreover, in cases where a user must animate more than one character simultaneously, one can specify the character that should perform the requested action by adding an additional method to the existing command for a character. Finally, in cases where a user must generate an animated character in a multitask scenario, by simply specifying the row in which the task should appear, the system will synthesize the tasks requested automatically.

We assume that the described unique functionalities that are implemented in CHASE will enable a user to synthesize compelling animated sequences in which a variety of virtual characters are involved. Hence, in view of the simplicity of the developed commands, in conjunction with the associated parameters, the proposed methodology is quite powerful in comparison with the previous solution. In addition, the easy-to-use and easy-to-

remember commands make the presented scripting environment effective, especially for users who are inexperienced in programming.

System Overview

This section briefly describes the proposed system. Specifically, a variety of background algorithms are responsible for recognizing the input commands and synthesizing the motion of a character. The developed background algorithms communicate with the animation system, which is responsible for generating a character's motion, as well as with a path-finding methodology to retrieve the path that the character should follow when a locomotion sequence is required. Finally, CHASE synthesizes and displays the requested motion sequence. Figure 2 represents the procedure.

Interface

The interface of CHASE (see Fig. 1) is characterized by its simplicity. In its current implementation, it consists of a scene panel that displays the resulting animations, an edit mode panel to edit the input objects, a progress bar that shows the progress of the displayed animation, a scripting box, and a few buttons for use in building, playing, and clearing the written scripts. Finally, buttons that save the scripted code and export the generated animated sequences are also provided.

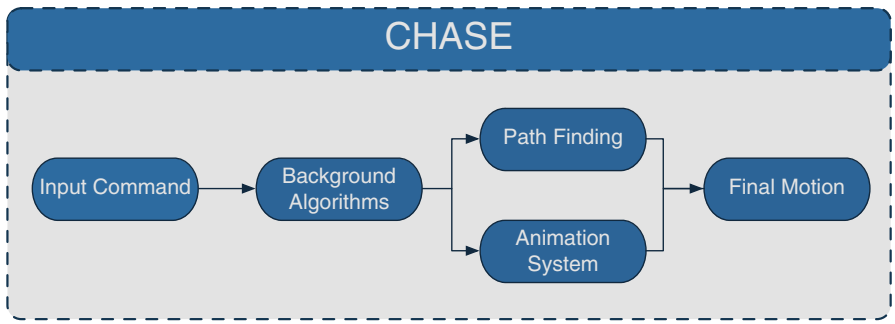
A downloadable version of the presented system, documentation specifying all of its capabilities, and examples of scenes can be found on the CHASE project page.

Third-Party Implementations

A number of techniques and libraries are used to construct CHASE. CHASE uses the Recast/Detour library (Mononen 2014) for the path-finding process and collision avoidance with the environment. Concurrent actions are generated based on a simple layering methodology similar to the one proposed in Oshita (2008). Finally, a similar (Lang 2014) full-body inverse kinematics solver was implemented to handle the postures of a character while interacting with objects located within the virtual environment.

Scripting Character Animation

Developing scripting commands for animating a virtual character can be characterized as a complex process since a virtual character should be able to perform variety of actions. In this section, the identifications of the basic scripting commands that are necessary to enable the virtual character to navigate and interact within a virtual environment are presented. Moreover, by introducing additional methods called by the main scripts, the system generates concurrent actions of a character, as well as animates multiple characters simultaneously. Finally, an additional functionality of CHASE for scripting multitask animated sequences for the generation of scenario-related animated characters is presented.



Character Animation Scripting Environment, Fig. 2 The architecture of CHASE

Identifying Scripting Commands

The application that is presented has been developed for users who are inexperienced in programming. Thus, simple, easily memorized scripting commands are necessary. To generate the required scripting commands, one must begin by identifying the possible actions or type of actions that a character should perform. Generally, a character should be able to perform simple actions such as waving its hand, tasks related to locomotion such as moving to a target position, and interaction tasks such as grasping with its hand an object that is located in the three-dimensional environment. It is apparent that these are the three basic types of actions that a virtual character should be able to perform. Based on this general description, three basic scripting commands were developed: the do(parameters), the goTo(parameters), and the interactWith(parameters).

The do(parameters) command provides a character with the ability to perform a single action. The goTo(parameters) forces a character to move within the given virtual environment. The final command is responsible for making the virtual character capable of interacting with a variety of tasks. Hence, the third command, the interactWith (parameters), is responsible for providing the ability to control a variety of the character's actions.

For these commands, the parameters within the parentheses indicate the possible parameters that each of the scripting commands could receive (see section Command Parameters). Due to the various parameters that each command receives, a user is provided with the means to develop both abstract and specified action of a character. For example, with the goTo(parameters) command, it is possible not only to generate the required locomotion of a character but also to enable a user to gain better control of the synthesized motion of a character, since the user can specify how the locomotion of a character should be generated. The following section presents the basic parameters that each command receives.

Command Parameters

A task assigned to a character can be performed in a variety of different ways. For example, a sequence of locomotion to a target position can be performed by walking, running, etc. motions. Hence, in cases where a user needs a higher level of control of the synthesized motions of a character, parameters that enhance these actual actions generated by the previously mentioned scripting commands should be defined.

The first command that implemented the do (parameters) command enables a user to script simple actions of a character. This command has a single mandatory parameter, which indicates the action that the character should perform. However, optional parameters to specify the body part or the duration of the task can also be used. Specifically, the user can request a single action by calling do(action), as well as specify the target where the action should be performed, the duration of the action, and the body part that should perform the requested action. This command initially permitted a character to perform the requested action without the need to perform a locomotion sequence (i.e., to wave its hand while staying in its position). However, the do(parameters) command can also be used to permit the character to perform locomotion tasks, since one can request that a character performs a walking motion. Based on these parameters that can be inserted into the do (parameters) command, a user has the means not only to generate the requested action but also to generate an action that should fulfill user-specified constraints.

The goTo(parameters) command enables the character to perform locomotion tasks. The user identifies a mandatory parameter, which is the target position that the character should reach. However, the user is also able to use an additional optional parameter that specifies the motion style that will animate the character. Therefore, a character's locomotion to a target position can be scripted either by (i) inserting the target position such as goTo(target) when a simple walking motion of the character is desired or (ii) inserting goTo(target, motion style) when both target position and motion style are specified.

The final command that is implemented in CHASE, the interactWith(parameters), can be characterized as more complex than the two previously mentioned commands. The reason is that

there are numerous possible interactions between a character and an object. If a character is asked to interact with an object, various actions can be generated. Even if it is possible to associate actions with specific body parts of a character in a preprocessing stage, there are also possible variations of the required actions. These variations may be related to the character's body or to the duration of the display of the action. For example, scripting a character to kick a ball may also require specifying the foot that should perform this action. Moreover, asking a character to knock a door may also require specifying the duration in the knocking. For that reason, four different parameters have been defined. The first two parameters (object name and interaction module) are mandatory. They indicate the object that the character should interact with and the interaction module that should be generated. However, depending on the user's requirements for generating a specific action, two more optional parameters could also be inserted. The first one (body part) enables the user to choose which of the character's body parts should perform the requested action. In the current implementation, the user is permitted to choose the hand or foot that will perform the action. The second parameter (duration) enables the user to choose the time (in seconds) required for the requested action.

Based on the possible parameters that each command could receive, the following should be noted. Firstly, while the user did not specify any optional parameter for a scripted command, the system generates the required action taking into account a predefined set of parameters that are associated with each action of the character. For example, if a user requests that a character kick a ball, the system will display only a single kick by the character. The reason is that a ball kicking action is defined as to be performed only once to avoid synthesizing meaningless and repeated motions. Secondly, it should be noted that each optional parameter is independent. This means that the user is not required to specify all of the optional parameters provided by each command. Therefore, the user may control specific components of the requested action.

A simple example of this capability of the commands illustrates this. While using the do (parameters) command, the user may request that only either the body part or the duration parameter or both of these be filled. In any case, the system's decision in generating the requested motion is not influenced by other factors since it is capable of recognizing the correct form of the scripted command in all of the aforementioned cases.

The three commands that are examined in this paper in conjunction with the associated parameters that can be used to animate a virtual character are summarized in Table 1. In addition, a small set of possible keywords that the user could employ in order to animate virtual characters is presented. It is assumed that an additional control parameter for the synthesized motion could be quite beneficial, since it enables the user not only to animate a character but also to force the system to synthesize the user's actual wish. Complete documentation of all possible actions that can be synthesized by the character can be found in the CHASE webpage (*URL omitted for review purposes*).

Scripting Concurrent Actions

Virtual characters, such as humans, should be able to perform more than one action simultaneously. This section presents the scripting process for concurrent actions that a character can perform. The concurrent action functionality is based upon the ability to specify the body part that should perform the action in conjunction with the base action that has been requested. The concurrent action lies between the do(parameters) and either the goTo(parameters) or the interactWith(parameters) commands. Specifically, to have a character perform concurrent actions, the do(parameters) command is attached to either the goTo(parameters) or the interactWith (parameters). A simple example follows. To cause a character to perform a motion, such as waving its hand while walking to a target position, the system permits the user to script the desired walking motion of a character and to request the additional motion that the system should generate. Hence, the previous example can be requested simply by scripting goTo(target, walk).do(wave hand, handR). Thus, by permitting the user to generate additional actions of a

character, while another action is in progress can, be quite beneficial when more complex animated sequences are required. Therefore, this additional functionality provides a higher level of control over a requested action of a virtual character.

Scripting Multiple Characters

In animated sequences, it is quite common for more than one character to participate in a single scenario. Hence, by extending the three scripting commands, CHASE also enables a user to script

more than one character simultaneously. This is achieved by attaching an additional command to one of the three basic commands, called characterName(parameter). This command specifies the character that should perform an action, permitting the user to control multiple characters, in cases where more than one character participates in the animation process. A simple example of forcing a specific character to perform an action follows. Consider a character named Rudy who is required to walk to target. This procedure could be called by simply scripting goTo(target). characterName(Rudy).

Scripting Multiple Tasks

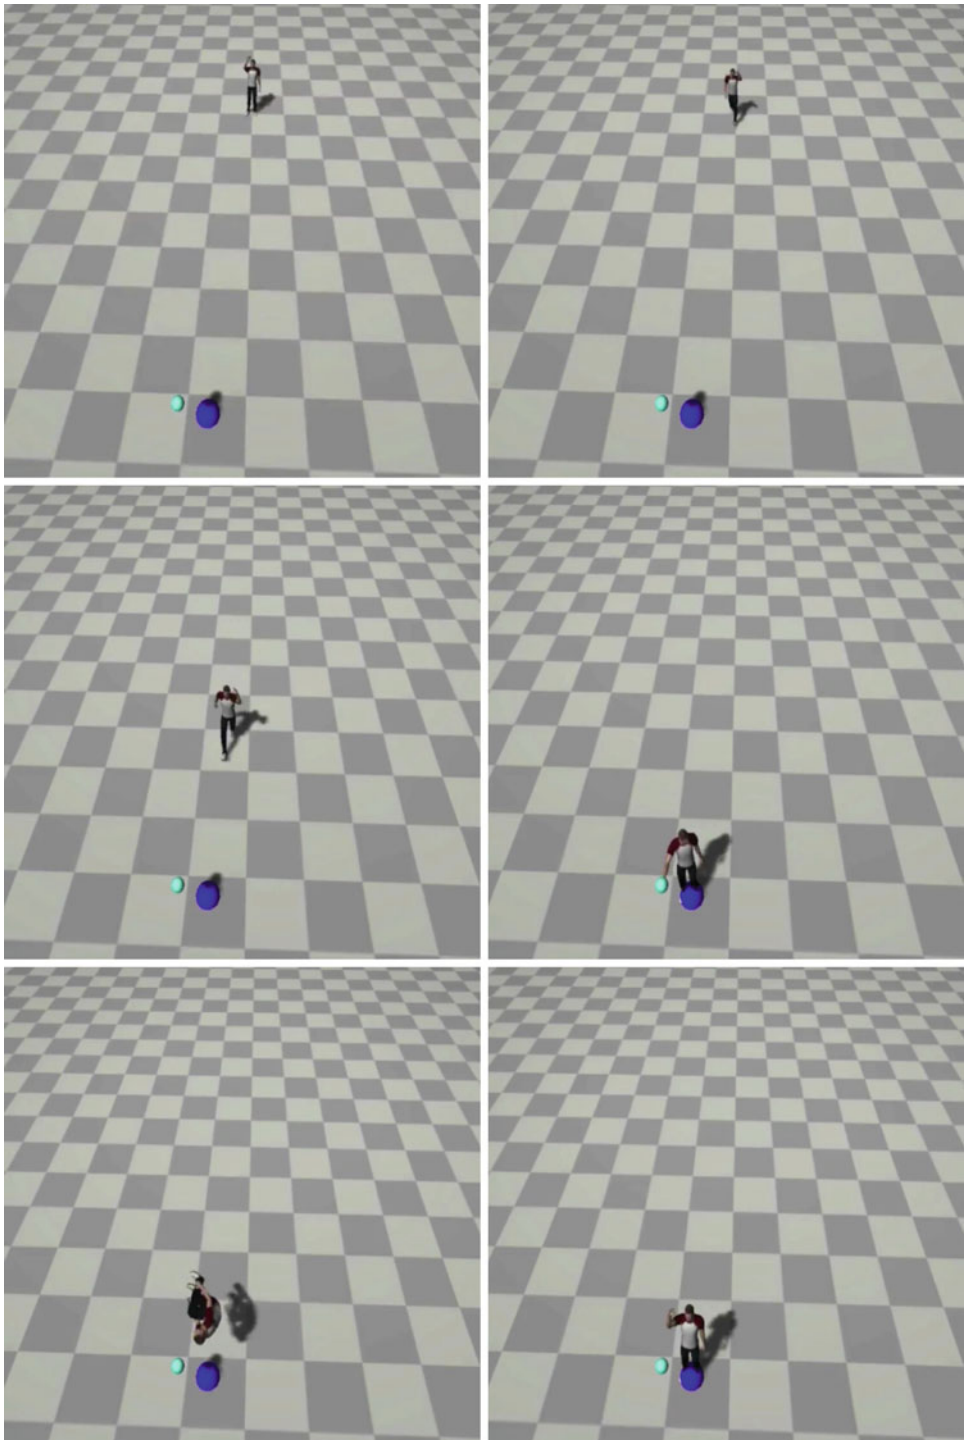
In scenario-related sequences that involve virtual characters, the latter should be able to perform a variety of tasks one after the other. Thus, this paper presents a method to script multiple tasks, such as enabling a user to synthesize long animated sequences. Generally, the tasks that a character can perform are characterized by their linearity. Specifically, a task begins while a previous task is completed, and the procedure continues until there are no other tasks for a character to perform.

Based on the foregoing, a multitask scenario in a general form can be represented as components of an array that has a dimensionality equal to $N \times 1$, where N denotes the total number of tasks that a character should perform. By assigning each of the actions an array called task[index], a user can generate long animated sequences. This is achieved by allowing the user to assign singe tasks at each index value of the task array. A simple example of a multitask scenario appears in Fig. 3, as well as in the accompanying video. Its scripting implementation is represented in Algorithm 1.

It is quite common in multitask scenarios to involve multiple characters. Two different approaches can be used in CHASE to script more than one character simultaneously in a multitask scenario. The first approach animates each character one after the other. This means that the action required of a characterB is generated after the action of a characterA has been completed. The reason is that each task of the characters taking part in the multitask scenario have been assigned a different index value of the task array. A simple example of generating the actions of two different characters appears in Algorithm 2. However, a user should be able to animate virtual characters simultaneously in multitask scenarios. This is achieved in CHASE by using a two-dimensional array named tasks[index][index]. In this array the first index value represents the row in which each action in generated, whereas the second index value represents the number of the character. It should be noted that each character should be represented by the same index value while developing a multitask scenario. Hence, the background algorithms that are implemented recognize and generate the requested tasks as separate entries. This enables the user to animate a number of characters simultaneously. A simple example in which there are two characters in a multitask scenario appears in Algorithm 3. It should be noted that a multitask scenario where multiple characters evolve in a general form can be represented as an array that has a dimensionality equal to $M \times$ N, where M denotes the total number of characters evolving in the multitask scenario and N denotes the total number of tasks that a character should perform.

Conclusions and Future Work

In this paper, a novel scripting environment, called CHASE, for use in animating virtual characters was presented. CHASE enables a user to request a variety of actions that a character can perform by simply using three commands. Each command, which receives a variety of parameters, is associated with specific actions that the character is able to perform. Moreover, the commands communicate with a variety of background algorithms that are responsible for generating the actions requested of the character. In addition to the scripting commands, by introducing three additional functionalities, the user is able to script concurrent actions of a character, multiple characters at the same time, and multitask scenarios in order to generate scenario-related sequences that involve animated characters.



Character Animation Scripting Environment, Fig. 3 A multitask scenario generated by using Algorithm 1

Character Animation Scripting Environment, Algorithm 1 A simple example for generating a multitask scenario

Data: input commands of a user
Result: the result animated sequence
task[1] = do(wave hand, handR, 3);
task[2] = goTo(ball, walk).do(wave hand, handL);
task[3] = interactWith(ball, punch, handR);
task[4] = do(jump);
task[5] = do(wave hand, handR, 2);

Character Animation Scripting Environment, Algorithm 2 By placing the actions of two different characters at different index values of the task array, the system generates each character action one after the other

Data: input commands of a user
Result: the result animated sequence
task[1] = goTo(ball, walk).characterName(characterA);
task[2] = goTo(ball, walk).characterName(characterB);

Character Animation Scripting Environment, Algorithm 3 A multitask scenario in which there are two characters. In this scenario, characterA moves to its target position while walking, and characterB moves to its target position while running. Finally, characterA punches characterB with his right hand

Data: input commands of a user
Result: the result animated sequence
tasks[1][1] = goTo(target, walk).characterName (characterA);
tasks[1][2] = goTo(target, run). characterName (characterB);
tasks[2][1] = interactWith(characterB, punch, handR). characterName(characterA);

Character Artificial Intelligence

Youichiro Miyake
Square Enix Co., Ltd., Tokyo, Japan

Synonyms

Character AI; Decision-making; Perception AI

Definition

A character AI is a system that makes decisions for what a character will do. Here, a decision means a strategy, tactics, or a certain behavior. Character AI does not only refer to the decision-making process, but also to the whole system used for dynamically connecting the character's AI and the game world. Such systems implement what is called as an "agent architecture" (Russell and Norvig 2016a). An agent architecture of character AI has three modules: perception, decision-making, and memory modules.

Introduction

In this entry, an overview on the history of the development of character AI is presented. Characters' AI techniques differ depending on the scale of the game. For small-size games, "scripted AI" is the most used method for controlling a character, whereby a scripted AI system uses script languages to issue commands that directly determine characters behaviors. For middle-size games, decision-making algorithms, such as rule-based systems, state machines, or behavior trees, are used. For large-size games, character AI is controlled by a large system based on an agent architecture with a perception module, a decision-making module, a motion-synthesis module, a memory module, and so on.

Drastic changes in character AI technologies came from the first 3D games made in the 1990s. In 3D games, characters must have their own artificial intelligence. Each character must have sensors and a body of its own and perform decision-making thinking. Characters with these traits are called "autonomous agents." From the late 1990s to 2010, the focus of character agent research shifted from scripted agents to autonomous agents (Miyake et al. 2017).

In the second half of the 1990s, research for character AI began at the MIT (Massachusetts Institute of Technology), and many robotics technologies have been applied for character AI in the game industry ever since. The MIT synthetic character group (MIT Synthetic Character Group 2003) has studied AI for virtual creatures. They introduced AI techniques from the field of robotics to autonomous agents in digital games. One agent architecture that they developed using a blackboard architecture is called the "C4 architecture" and is shown in Fig. 1 (Isla et al. 2001; Burke et al. 2001). The main feature of this model is to separate intelligence modules and memory modules. Their research results were presented in GDC 2001, and it had a profound impact in the game industry. For example, Halo 2 and F.E.A.R. (2005, Monolith Productions) used this architecture (Orkin 2005, 2006).

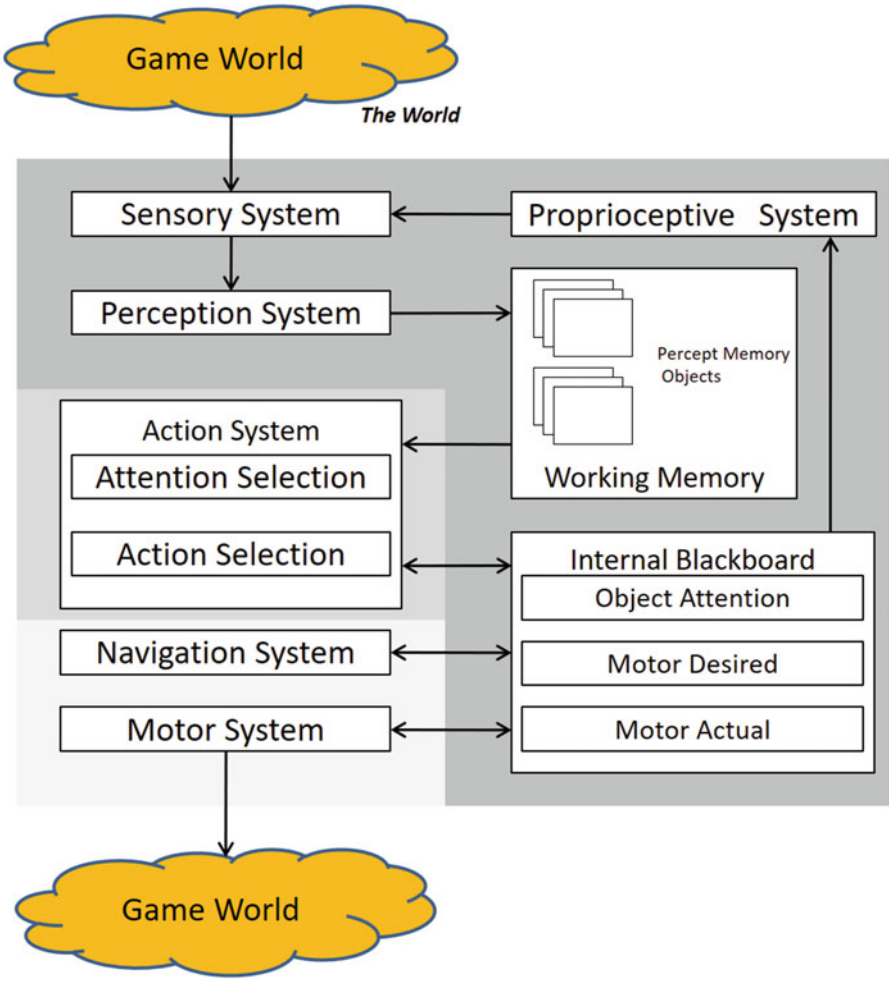
Similar to a C4 agent architecture, generally an agent architecture for a game character consists of several software modules, such as a sensor module, a recognition module, a decision-making module, a motion-making module, and an effector module. A system that employs a sensor module and a recognition module is called a "perception AI" system, which is used for recognizing the environment in the game (see section "Perception AI"). The decision-making module is the largest module and is used for making decisions using certain decision-making algorithms, such as rule-based, state-based, behavior-based, utility-based, goal-based, task-based, and simulation-based decision-making algorithms (Miyake 2017) (see sections "Decision Making for Game Characters" and "Memory and Knowledge Representation").

Perception AI

A character in a digital game must recognize the environment around itself in real time to respond to changes in the world. However, it is impossible for a character AI to recognize the game world directly, because it would be an excessively heavy load for an AI agent to analyze and understand the environment around itself from its point of view in real time. Perception AI systems are used to help character AIs to recognize the environment in the game.

The role of perception AI is to acquire information of the environment via physical simulations, such as ray-casting and sound propagation, and to abstract an essential whole-world image from this information. Perception AI essentially means how the game world is seen from the point of view of a character.

Perception AI uses efficient methods to acquire information of objectives and terrain from a game stage. All objectives contain information that they use to represent themselves. For example, a rock in a game would have properties such as "rock," "breakable," and "movable," and a door in a game would have properties such as "door," "open," and "can go through," and so on. In Halo 2, the battlefield of the game is divided into three parts, namely the front area, the middle area, and the back area. A representation of objectives is called a knowledge representation (KR), and a

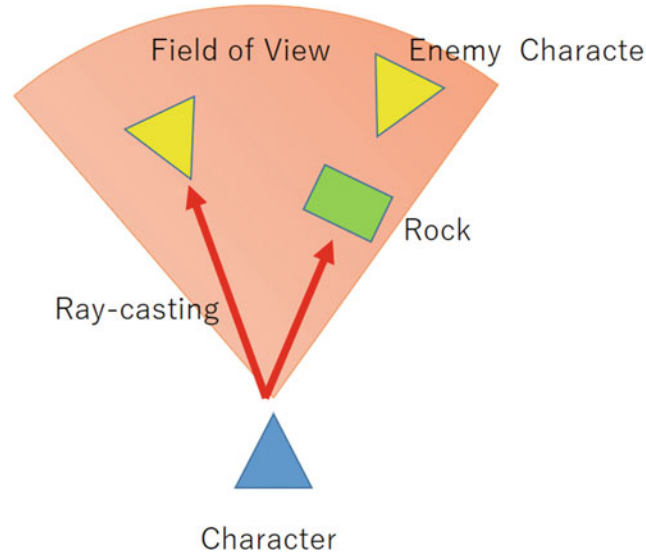


Character Artificial Intelligence, Fig. 1 C4 architecture (Isla et al. 2001; Burke et al. 2001)

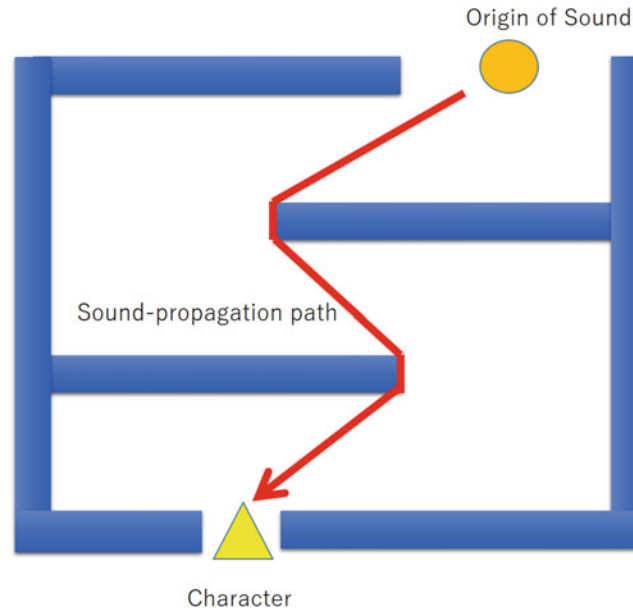
representation especially for terrain and space is called a world representation (WR). By using KR and WR information, a character can recognize its present situation.

Perception AI involves sensor modules for performing specific simulations and may include five modes for representing the five human senses. Visual sensors are the most important in digital games because the human player's actions also depend on the player's sight. In general, the visual sensors of a character have visual regions called "field of vision," as shown in Fig. 2. When an object enters the field of vision, one or multiple rays are casted onto the object. If the ray can go through and reach the object without any collision with other objects, it means that the character can see the object. This is the principle behind visual sensors.

In stealth-based games in particular, perception AI is very important. Stealth-based games are games in which the player generally breaks into a building while hiding from enemies. All enemies have vivid perception AI. For example, in Splinter Cell: Conviction (Ubisoft 2010), each enemy has a field of view in the shape of a coffin because this shape is very useful for being able to see the deepest and farthest region of narrow rooms. In Final Fantasy XV (SQUARE ENIX



Character Artificial Intelligence, Fig. 2 Vision sensor with a field of view



Character Artificial Intelligence, Fig. 3 Sound propagation

2016), each character has two visual regions consisting of a forward circular sector and a backward circular sector. The forward circular sector can recognize objects clearly, whereas the backward circular sector has ambiguous recognition functions for vaguely noticing objects.

To implement hearing, the easiest way involves the use of a spherical sound source with a certain radius around a character. This sphere is used to determine if a character can hear the sound coming from the origin. Furthermore, in some stealth-based games, as shown in Fig. 3, sound-propagation simulations are performed to confirm the existence of a sound path through space from the origin to a character by connecting the edges of walls. Moreover, in Sprinter Cell: Blacklist, sound propagation was implemented. The shortest path for sounds is calculated by connecting the edges of walls (Walsh 2014). In Hitman (Io-Interactive 2016), sound propagation

is calculated via diffraction and transparency (Rørbech 2015).

And typical collision or overlapping sensors are used for character's touching to objects.

Decision-Making for Game Characters

The decision-making algorithms used in digital games can be classified in seven types, namely rule-based, state-based, behavior-based, task-based, goal-based, utility-based, and simulation-based algorithms (Fig. 4).

In the 1980s, almost all games used rule-based algorithms to control characters, as in, if the player's position is to the right, then go left. Some rules were prepared, and one rule was selected to be executed after evaluating all rules. Even now, rule-based algorithms are very popular for small- and middle-size (sometimes even big-size) games. For example, The Sims 3 (Maxis 2009) uses rule-based methods to control NPCs (nonplayer characters) by preparing and executing multiple action rules (Evans 2010).

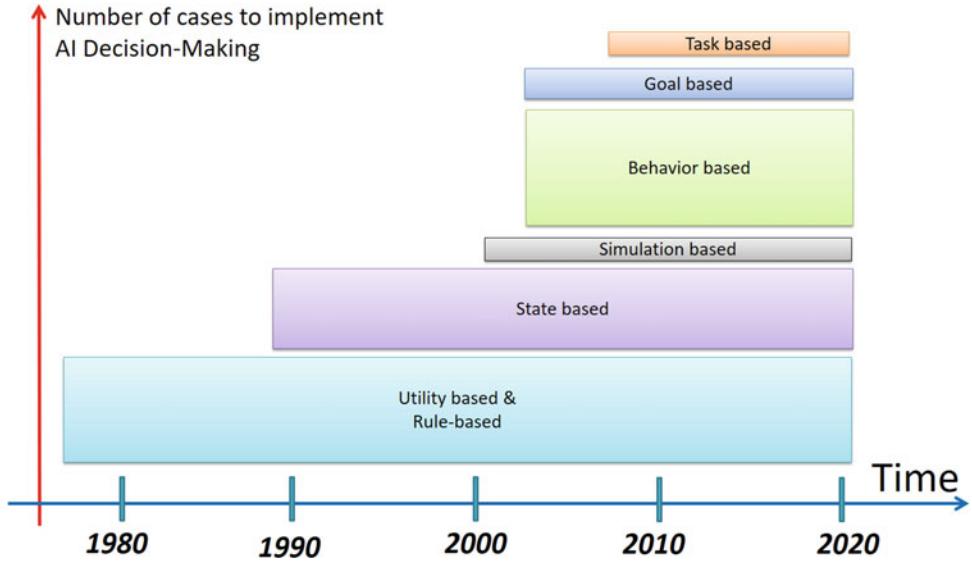
In the 1990s, especially in the first 3D games, state-machine methods became popular. State-machine methods are suitable for describing a character's behavior and its transitions in 3D space. Many game developers made original state-machine GUI tools, and some middlewares were supported by AI middleware companies. For example, character AI in Uncharted 2: Among Thieves (Naughty Dog, LLC, 2009) is based on a state-machine system (Gregory 2009) (Fig. 5).

Utility-based algorithms represent a method for selecting one option from many by calculating their value. For example, a character may have many actions that they could execute in a given situation. The character's AI selects one action out of all possible actions by calculating their corresponding utility value. Utility can alternately mean "effectiveness" or "evaluation value."

Behavior-based algorithms began to be used for character AI in Halo 2 in 2004 (Isla 2005a, b). In Halo 2, a new method called "behavior tree" was developed for character AI by Damian Isla, the AI lead of the game. A behavior tree is a hierarchical acyclic directed tree that originates from a root and reaches behaviors, as shown in Fig. 6 An advantage of behavior trees is their scalability, by which users can modify a behavior tree without having to perform complex

Decision Making Algorithm	Features	Game titles
Rule-based	Rules are listed, and one of them is selected.	The Sims 4 (Maxis, 2014), etc. All classic games
State-based	States are connected by transition conditions.	Uncharted 2 (Naughty Dog, 2009), etc.
Behavior-based	Behavior tree	Halo2 (Bungie, 2004), etc. Many modern games
Utility-based	Evaluating choices	The Sims (Maxis, 2000), etc. Many classic games
Goal-based	Goal first. A goal is decided, and how to achieve is considered.	F.E.A.R. (Monolith, 2005) Chrome Hounds (FROM SOFTWARE, 2006)
Task-based	Hierarchical Task Network	Killzone 2,3 (Guerrilla Games, 2009, 2011)
Simulation-based	Simulating a character behavior in a space	Racing games, robotic games, etc.

Character Artificial Intelligence, Fig. 4 Comparison of seven decision-making algorithms



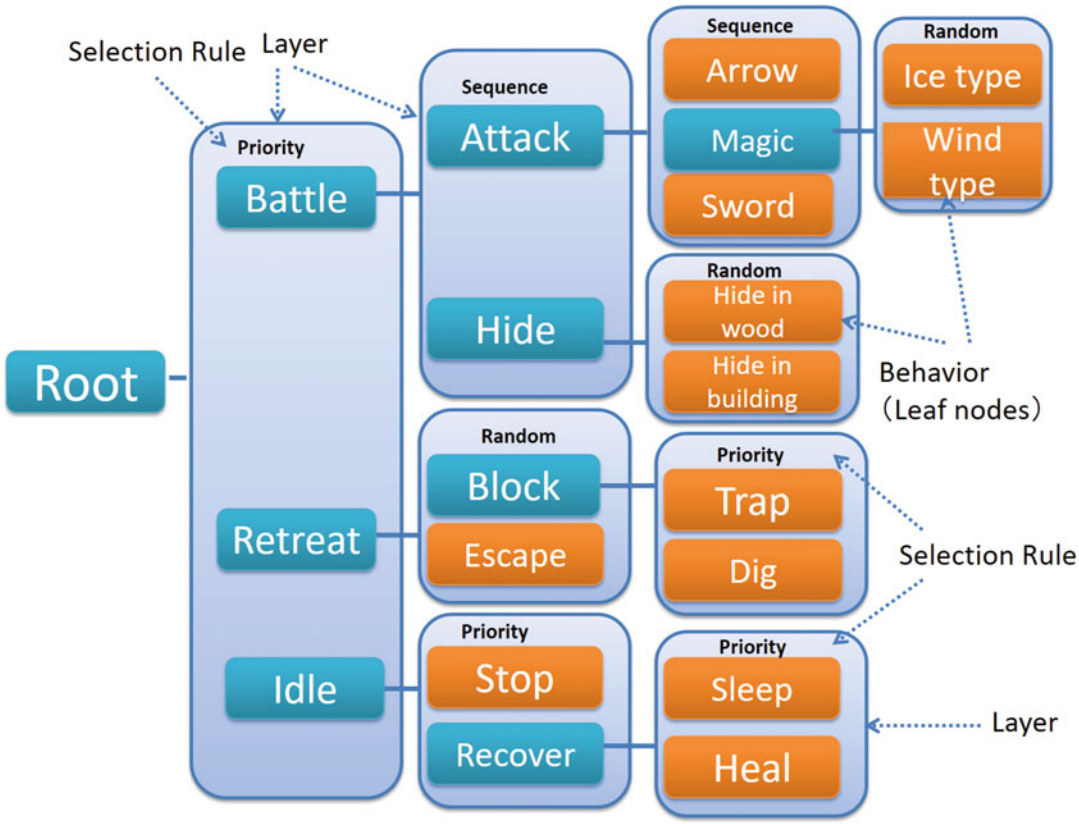
Character Artificial Intelligence, Fig. 5 Time table of decision-making algorithms

operations. When one state is added to a state machine, all the connections between the new state and old states must be considered. However, when one node is added to a behavior tree, only the local structure around the new node has to be considered. Behavior trees have become the most popular algorithms in the game industry. In more than 70% of big-size and mobile games, at least one behavior tree is used.

Behavior trees have a layered architecture. Each layer of a behavior tree has several child nodes and one selection rule. Each layer selects nodes to be executed via the selection rule. First, for each behavior, the tree judges whether it is possible to execute that behavior or not under the current situation, and the nodes that are deemed unfeasible to become active are removed from the selection process. Then, nodes are selected based on rules applied to the remaining ones. Based on the selection rules, the selection process unfolds. For example, a layer with a "sequence rule" executes its nodes in a certain order according to priority. On the other hand, layers with a "priority rule" attempt to execute only one node with maximum priority out of all the nodes that could become active. Layers that employ a "random rule" execute one node selected at random.

Goal-based algorithms began to be used in 2004. For example, F.E.A.R. uses goal-oriented action planning (GOAP). GOAP is a kind of STRIPS (Stanford Research Institute Problem Solver) developed in the 1970s. Usually, this solver is used for making long static plans. However, Jeff Orkin applied STRIPS to the real-time planning of characters' actions by chaining many actions, which are described by a precondition, an action, and a postcondition, to produce a long actions plan (Orkin 2005, 2006).

Task-based algorithms are the most promising for the future of game AI because they can be used to develop the most complex thinking patterns for character AIs. Hierarchical task networks (HTNs) are decision-making algorithms for making plans similarly to node networks. They were developed in academic research in the 1990s (Russell and Norvig 2016b). HTNs have domains and methods. A domain means a collection of tasks, which represents a region of a problem. Methods divide one task into smaller tasks in a domain. HTNs have hierarchical methods and domains. A task which can be resolved into subtasks further by its method is called a composite task, and a task



Character Artificial Intelligence, Fig. 6 Behavior tree

which cannot be resolved further is called a primitive task. Killzone 2 and 3 (Guerrilla games, 2009, 2011) used HTNs (Straatman et al. 2009, 2013; Champandard 2008), and a few other companies used them.

Simulation-based algorithms are used for solving complex problems that cannot be transformed into more easily solvable problem. In such cases, simulation-based methods are very effective. For example, when an AI car goes through a narrow cave, it tests some combinations of turns and accelerations to find the best combination for moving smoothly.

Although there are seven types of decision-making algorithms, only one or two algorithms are used in each game. The design of decision-making systems and tools is done by engineers, whereas implementing decision-making thinking using those tools is done by the game designer. For example, there are many different behavior tree tools made by different game companies, and many game engines contain proper decision-making tools.

Memory and Knowledge Representation

A character's AI stores information on its memory. The information stored in this memory can have many knowledge types, which are referred to as knowledge representations (KRs), as explained in the section "Perception AI." Any knowledge has a form of KR.

For game characters, it is difficult to recognize terrains, objects, or facts in the game by themselves. Knowledge representations of all the things that a character must recognize are prepared during game development so that characters can recognize the game world via KRs.

A character's memory is basically a collection of variables. However, in highly developed AIs, memory must be formatted via KRs.

For example, in Halo 2, some objects have "affordance" information (Isla 2005b). Affordance is a concept that indicates possible activity. It is a term used in cognitive psychology for concepts such as eatable, movable, breakable, and so on. If the KR of an object is "movable," the character recognizes that the object can be moved by referring the object's KR.

In F.E.A.R., the KR of characters is more sophisticated and is called a World Memory Fact (WMF). A WMF has a unified data structure (Orkin 2005):

```
WorkingMemoryFact
{
Attribute<Vector3D> Position
Attribute<Vector3D> Direction
Attribute<StimulusType> Stimulus
Attribute<Handle> Object
Attribute<float> Desire
 ...
 float fUpdateTime
}

Attribute<Type>
{
 Type Value
 float fConfidence
}
```

(This is C++ code to define the WMF data type. Each piece of information has a confidence value.)

Another notable example is Gunslinger (2002, not released, Surreal). The title was not released, but it exerted much influence in the KR implementations of subsequent games. This title also had KR for facts in the game. The KR of an event had components, such as Subject Group, Verb, Object Group, Object Individual, Magnitude, Where, When, and Template (Alt and King 2002). First, any event that was seen by a character was registered in the global memory with an ID. The characters who saw the event had a reference to the event's ID. For example, assume that Joe was killed by the lawmen in the square at noon. This fact is remembered by an event manager, and each witness of that fact has a reference to the event stored in the event manager. Each event has a reference counter that indicates the number of witnesses who remember the fact. When a witness is killed, the reference counter is reduced.

Conclusion

Character AI represents one of the cores of a digital game's AI. Many AI and robotics technologies are integrated in character AI technology. During the early stages of character AI development, many robotics technologies were employed. However, the speed of the technical progress of character AI has been very fast, such that AI technologies originally taken from robotics have been developed in the game industry more than in the robotics industry. In the near future, character AI techniques developed in the game industry will be used in fields involving digital characters other than gaming. Further into the future, more learning or evolution systems will be introduced and partially replace these decision-making systems.

The reason for this is that character AI can be simulated in a game world without involving real bodies and avoiding physical troubles. Thus, a game world can be regarded as a cradle where characters can be developed at a fast speed.

Synonyms

Children Protection Engine; Toy Privacy

Definition

The children privacy protection aims to enable parents or guardians to be in control of their children's privacy by specifying their privacy

preferences for a toy, under the assumption that the toy has published an accurate privacy policy and complies with it in a privacy protection engine attached to the toy.

Privacy Protection Laws

Referring to the direction of the United States Federal Trade Commission (FTC), Children's Online Privacy Protection Act (COPPA 1998), and the European Union Data Protection Directive (EUDPD), a child is an individual under the age of 13 years old (Hung 2015). Children privacy protection aims to protect children's personal information, which is particularly sensitive, especially when associated with their real identity. Children provide a unique user base which requires special attention in several key areas related to their privacy (Hung et al. 2016). In general, children do not understand the concept of privacy, and hence, they tend to disclose as much information to people they can trust (Rafferty et al. 2017). In this context, the COPPA indicates that to protect children privacy, a child's personal information cannot be collected without parental consent.

Smart Toys Privacy

Nowadays, many toys on the market are becoming integrated with the sensory and networking capabilities of mobile technology, introducing new threats to privacy for children who are the primary users of these devices. Online privacy for children has been a great concern in this environment, particularly when the child's private information is involved and can be potentially shared with other parties. For example, an invention called "Google Toy" has caused many criticisms from the media as people express concern about possible privacy breaching by Google, especially with their children at home. Mattel's "Hello Barbie" has been criticized for the negative effects on children along with privacy concerns since its introduction in February 2015. In December 2015, Mattel was sued in California by two mothers to allege that Hello Barbie records their daughter's conversations without parental consent, in violation of the COPPA in the United States. Serious concerns about privacy and data security are raised by the personally identifiable information (PII) that is collected by these smart toys. These concerns are crucial since collected data involves sensitive children's information (Tang and Hung 2017).

Privacy Consequences and Precautions

While smart toys provide new educational and entertaining values, experts have warned consumers of the data security and privacy issues of these toys. A recent United States Senate report (Nelson 2016) states that these toys may gather a child's personal information, which may potentially cause serious consequences such as identity theft. Parents should be aware of the information a toy is collecting about them and their child. For most parents, it is difficult to evaluate policies regarding data collection and use since they are not usually experts with respect to data privacy and security. However, parents must find a way to reject smart toys that do not provide information about how a toymaker collects, uses, and secures their children data.

Toy Industry and Privacy

The usage behavior of children indicates that they are more open to giving out personal information, which makes issues of sensitive data sharing of great concern. The North American Toy Industry Association (TIA) released a white paper regarding the changing privacy and data security landscape the toy industry is facing with the emerging popularity of child-directed mobile apps. The TIA iterates the issues of children's marketing and privacy in this context, indicating that privacy and data security issues affect day-to-day operations of toy companies. The toy industry has also issued regulations for toy safety; however, these regulations have no mention of privacy (Hung 2015). A report from Pew Research Center and Berkman Center for Internet & Society at Harvard University indicates that most parents in the

United States are concerned about their children's online privacy, some of the main concerns being related to strangers online, and the data advertisers are collecting about their children's online behavior.

Children Protection Engine

Privacy can result in physical safety of child user, e.g., child predators. While parents strive to ensure their child's physical and online safety and privacy, they may wish to be in control of how their personal data is shared through the devices they are using. However, there is no standardized child protection model for parental control in this paradigm (Fantinato et al. 2018). Parental control is a feature in a smart toy for the parents to restrict the content the children can provide to the toy. The children privacy protection aims to enable the parents or guardians to be in control of their child's privacy by specifying their privacy preferences, under the assumption that the toy has published an accurate privacy policy and complies with it in a privacy protection engine attached with the toy (Salgado et al. 2017).

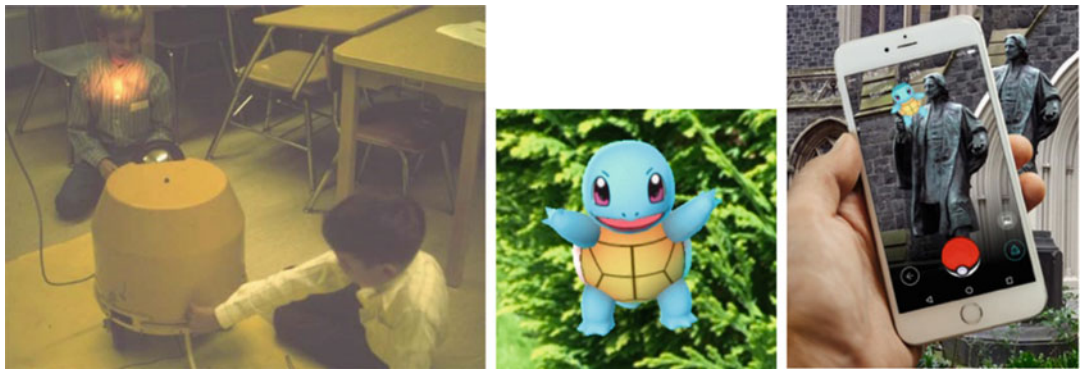
Children's Games, from Turtle to Squirtle

Krystina S. Madej
Georgia Tech, Atlanta, Georgia, USA

MIT 1967, *Pokémon GO* 2016

We are acutely aware that children use media all day, every day and that a part of that use is playing video games. Today four out of five US households own game consoles (Lofgren 2016) and in 2017 sales of children's mobile games alone are expected to reach $2.2 billion (Children's Mobile Game n.d.). In 2013, 38% of children who were 2 years old used mobile devices; in the two previous years, the rate of use for two to four-year-olds climbed from 39% to 80% (Rideout 2013). Now a 91 billion dollar business worldwide

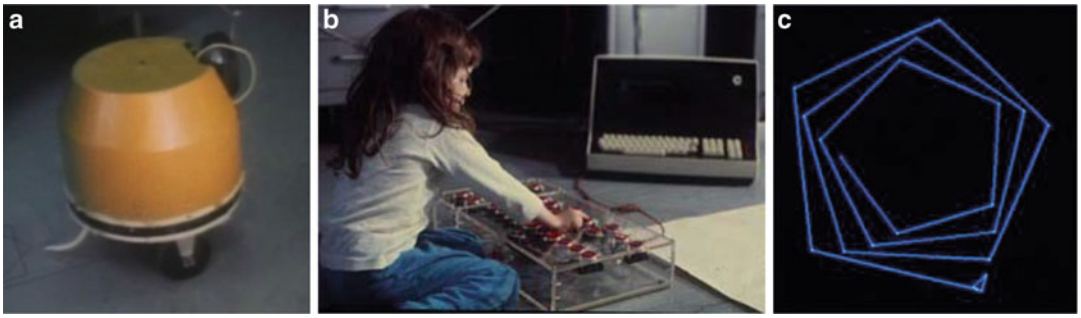


(2016) (Fuscaldo 2016), video games were first developed barely 60 years ago. Adults have long used children's games to entertain as well as educate. Plato's comments in *The Republic* (380 bce) on the value of structured play for developing young children into socially responsible and well-adjusted adults, John Locke's entreaty in *Some Thoughts Concerning Education* (1693) to make education entertaining because children "love to be busy, change and variety are what they delight in; curiosity is but an appetite for knowledge," and John Dewey's proponing in *Democracy and Education* (1922) that children learn best through experience, demonstrate to us society's ongoing desire to take advantage of children's proclivity to learn as they play (Madej 2016). It's not surprising then that children's video games had their start with a desire to use technology to benefit learning. It is also not surprising that, on their own, children prefer to accentuate entertainment over education.

Since the late 1960s, when the first programming language for children was developed at MIT, until today's mixed reality applications, games for children have travelled a continuum committed to both learning and entertainment objectives. The brief history that follows shows children's games as evolving from two different beginnings: computer applications with educational objectives for specific age groups and computer and console games designed to entertain a wide audience. The differentiation between children's and adult's games is difficult to establish because of children's facility with technology, the social nature of playing games, whether with older siblings, parents, or other children, and the nature of some games that can be played across age groups. Too, children are precocious – their nature is to challenge themselves with new things; they seldom stay within their age category for long for any activity. As an important market, children have been a motivating force in the evolution of game genres. While not all genres are covered in the following history, those discussed are representative of innovations in technology and shifts in interest that have encouraged change. These include early educational and arcade style games, handheld games, massive multiplayer online games, active games, augmented, virtual, and mixed reality games. Our trajectory takes us from the first LOGO Turtle to today's augmented reality *Pokémon Go* Squirtle.

1960s: The Very Beginnings – *LOGO* and Education Through Constructive Play

Computer play environments developed specifically for children date back to Seymour Papert and *LOGO*, the programming language released in 1967 that he and colleagues developed at MIT. Papert had studied with the child psychologist Jean Piaget in Switzerland and considered the computer an ideal tool for *learning by doing*. Using *LOGO,* children as young as three controlled a "Turtle" to create graphics (Fig. 1) (Blikstein n.d.). The program proved to help



Children's Games, from Turtle to Squirtle, Fig. 1 (**a**) First Turtle. (**b**) Buttonbox for preschoolers. (**c**) LOGO graphic

children learn complex notions qualitatively, more deeply, and with less effort (Papert et al. 1979). Papert's work was highly influential and encouraged the use of computers and software programs as a supplement to work in schools. *LOGO* spawned a number of research innovations that moved out of education and into entertainment including *LEGO Mindstorms,* a robotic system of LEGO bricks that had children building robots with motors, lights, and sensors.

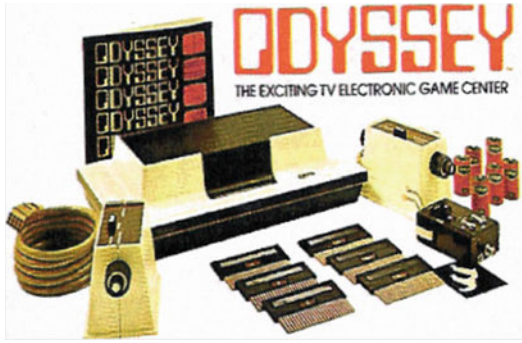
Early Interest in Education and Entertainment

Educators found that children were drawn to the active engagement computers offered and became interested in providing their students with subject-based programs to take advantage of this increased eagerness to learn. They were supported by educational organizations such as the *Minnesota Educational Computing Consortium* (*MECC*), which developed statewide systems for learning about how to use new technologies and software applications for different age groups, grade levels, and subject categories (For more information on MECC see Jancer (2016). For a list of programs available through MECC in 1983 see Atari Program Exchange Catalog (1983)). To reinforce learning at home, *MECC* sold its school software to parents and by 1983 offered more than 150 subject-related applications for children age three-and-up in its annual catalog. One of its popular school offerings, *Oregon Trail* (1978), a game about settlers who made the difficult pioneer journey from Independence, Kansas to the Willamette Valley in Oregon, became a notable success when it was released to the general public as a game title in 1985 (Wong 2017). Other programs that became popular included *DinoPark Tycoon* (1993) and *StoryWeaver* (1994).

In 1972, the first home console system, *Odyssey Home Entertainment System*, offered entertainment games based on the simple mechanics of moving light blips across the screen with a controller. Plug-in programs changed how these blips reacted to the control units and created different games. Players attached gameboard overlays to the television screen and could play, among other games, *Tennis, Hockey, Football, Cat and Mouse*, and *Haunted House* (Fig. 2). Educational topics were also included: players could, for instance, learn the names of the US states. *Odyssey* games included poker chips, play money, and score cards that completed the game play experience. The system inspired *Atari's* Nolan Bushnell to create *Pong*, the popular game in which players use paddles to hit a ball back and forth (Winter 2013).

Edutainment

By the early 1980s, PCs began selling in the millions and were being advertised as *family*

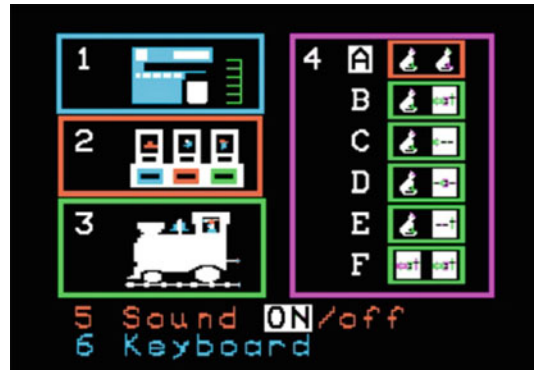


Children's Games, from Turtle to Squirtle, Fig. 2 The *Odyssey Home Entertainment System* (1972)

Children's Games, from Turtle to Squirtle, Fig. 3 Family computer systems were advertised for both education and entertainment

computer systems that could be used both for education and for entertainment. Ads often showed parents playing together with their children as a family. Video games were on their way to becoming a fixture in children's daily lives (Fig. 3).

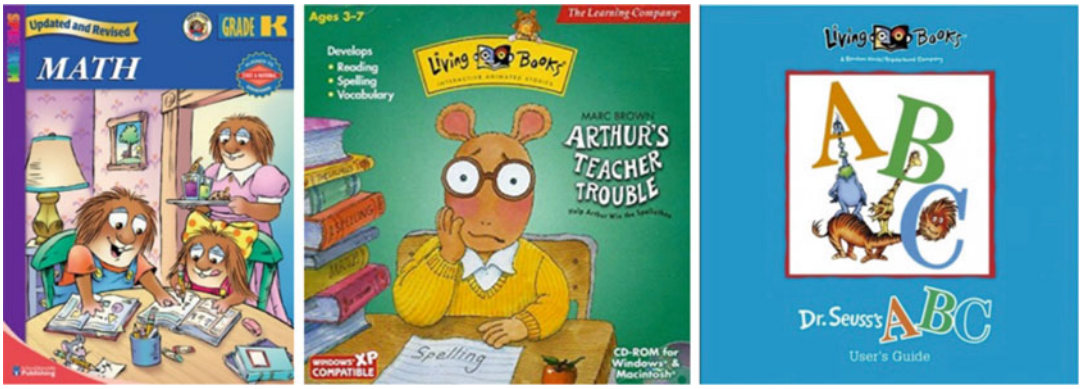
Publishers and game developers noted the success of education-related titles and began to intentionally combine entertainment games and education software to create *edutainment*, software that could be marketed as both entertainment and education. *The Learning Company* and *Broderbund* were two companies that began to create and promote entertainment-based educational games from different perspectives that still prevail. The Learning Company was started as an educational software developer. Its first commercially developed edutainment title, *Reader Rabbit* (1983), designed for elementary school children



Children's Games, from Turtle to Squirtle, Fig. 4 *Reader Rabbit*: Menu Screen (1984)

by cofounder Dr. Leslie Grimm, set the pattern for educational series. Using stills, simple animation, and music, the click and point games engaged children in learning about language. Children picked individual letters, or combinations or sequences of letters, to complete activities and were rewarded with a jumping/tumbling bunny and congratulatory sounds (Fig. 4) (Reader Rabbit and the Fabulous Word Factory n.d.). Successful Learning Company titles included *Clue-Finders, Mind Power, Zoombini's*, and *Super Solvers*. Each targeted a specific age-group and a subject area (The Learning Company n.d.). The company aimed to interest parents in improving their children's skills and knowledge.

Broderbund (1980), on the other hand, started as a commercial game developer (*Prince of Persia, Myst).* It moved into edutainment titles in 1985 with the detective game *Where in the World is Carmen Sandiego*. The company's approach to edutainment was story rather than arcade-skill based: in Carmen Sandiego children were set the task of finding Carmen and travelled around the world asking questions that would lead them to the thief. This narrative approach had more in common with text adventures than with arcade action. After the initial success with *Carmen*, Broderbund founded *Living Book*s, a series of interactive CD-ROM storybooks that engaged children through click and point animations. It brought well-loved print stories – Mercer Mayer's *Just Grandma and Me* (1992), Marc Brown's *Arthur's Teacher Trouble* (1992), Stan



Children's Games, from Turtle to Squirtle, Fig. 5 Lil Critter helps his sister with her math, Arthur worries about his spelling, Dr. Seuss's ABC's

and Jan Berenstain's *The Berenstain Bears Get in a Fight* (1995), *Dr. Seuss's ABC* (1995) – to an audience who enthused about the new game-like interactivity in these stories. Game publishers soon adopted popular story characters to bring their appeal to education-related topics such as reading, writing, math, art, puzzles, and thinking (Fig. 5).

Evolving Entertainment and Edutainment for Computers and Consoles in the 1980s

Entertainment games evolved along two main paths in the late 1970s – as arcade-action games and as text adventure games. In an arcade-action game, although the game might consist of cause and effect events, it did not require a story to be successful. By the early 1980s, original *Pong* action had evolved and included: maze games – *Pac-Man* (1980), players needed to avoid four ghosts while eating up all the dots; platform games, called climbing games at the time – *Donkey Kong* (1981), players jumped obstacles and enemies through four different levels; and simulation games – *Star Trek: Strategic Operations Simulator* (1982), players had to defend the Starship Enterprise from Klingon invaders.

Text-adventure games, on the other hand, were based in story. Players achieved their goals not by repeating arcade-type actions but by asking questions of game characters, unlocking secrets, and overcoming obstacles to reach a goal. As *Spacewar!* (1962) gave rise to all later action games beginning with *Pong*, *Adventure* (1975) became the first text adventure game that spawned all other text adventures. Popular in university and corporate intranets, *Adventure* was initially created to be shared with children. Will Crowther, the designer, writes "I decided I would fool around and write a program that was a re-creation in fantasy of my caving, and also would be a game for the kids [his two daughters], and perhaps some aspects of the Dungeons and Dragons that I had been playing…. The kids thought it was fun" (The origins of "Adventure," Crowther n.d.).

As the game market grew and as technology evolved, exploration in different game-like experiences for children increased. When *HyperCard*, an easy to use software programming tool was introduced by Apple in 1987, Amanda Goodenough used it to create *Inigo Gets Out* for younger children. This first graphical hypertext lets children explore a space the cat *Inigo* inhabits and move the story forward by clicking not on the object of action (i.e., the cat), but on where the object needs to move. For instance, clicking at two birds will make *Inigo* jump at them. Published by *Voyager,* the simple narrative opened the eyes of artists and designers, as well as writers, to the possibilities of making their children's stories interactive (Fig. 6) (Madej 2007).

While Goodenough, a writer, was creating with hypertext for young children, Roberta Williams, a game designer, was developing the first edutainment graphical adventure game, *Mixed-up Mother Goose* (1987), to entertain and educate her two preschoolers. Williams had set up *Sierra Online* with her husband Ken and they had created the 10+ adventure series *King's Quest* (1984). Based in stories, many adapted from traditional fairy tales or adventure tales, *King's Quest* was the first game to introduce third-person play; until that time players played in the first person. The third-person position allowed the player an important choice – to think about the character either as her/himself, or as a separate character altogether (DeMaria and Wilson 2002). In *Mixed-up Mother Goose* young children play as one of eight characters that searches for lost items throughout the land and returns them to help story characters out of their predicament, i.e., they could help Mary by bringing back her lost lamb (Fig. 7). When completed successfully, the task was rewarded by a congratulatory animation/sound. In contrast to *Reader Rabbit* published four years earlier, children could visualize themselves in the story through the avatar, could explore the space, and could interact with story characters. Other mechanics such as picking up the clue, dropping it off, and being rewarded by an animation were based on existing types of actions. Together these sets of click and point actions became characteristic of children's games, and indeed of many adult games.

Children's Games, from Turtle to Squirtle, Fig. 6 *Inigo Gets Out* title screen

In 1986, *Walt Disney* released *The Black Cauldron* based on its animated film of the same name. The company made the game to be more child-friendly than other games of the time; designer Al Lowe simplified the game commands by replacing the text parser with function keys to make it easier for children to play the game, an innovation not used again for a number of years. Lowe followed the original story and provided more decision-making choices by adding new plot branches and six endings. Sierra's expertise in graphics made the game visuals more realistic and appealing than the linear and stark graphics of other games (Fig. 8) (Lee and Madej 2012).

Animated movies were a natural source for children's action-based games as their storylines already consisted of action that designers

Children's Games, from Turtle to Squirtle, Fig. 7 *Mixed-Up Mother Goose* of the rhyme, *Mary Had a Little Lamb*

Children's Games, from Turtle to Squirtle, Fig. 8 *Black Cauldron* graphics (*left*) versus *Dark Crystal* graphics (*right*)

could mine. The puzzle game *All Dogs Go to Heaven* (1989), the side-scrolling platform game *Aladdin* (1993), and the action-adventure *Casper* (1996) featured only action sequences rather than the entire story. Live films were also used to inspire action adventure games suitable for children. As is the case with animated films, most games use the story plot only loosely to take players through action sequences. In *The Karate Kid* (1987), for instance, the player uses karate moves on four levels and ends with Master Miyagi congratulating him/her on learning the moves needed to help Daniel successfully meet all the challenges (See a partial list of movies made into video games at https://en.wikipedia.org/wiki/Category:Video_games_based_on_films, Great video games based on movies n.d.).

The first video game that featured animation as polished as in animated movies was *Disney Interactive*'s *The Lion King Animated Story Book* (1995). Media Station, the developer, used breakthrough technology and skillful editing to ensure the original quality and continuity while affording interaction. Designed for children 3–8, the game became popular with children as well as adults who had enjoyed the movie. Other *Interactive Storybooks* based on Disney animated films followed: *Winnie the Pooh and the Honey Tree*, *Pocahontas*, *The Hunchback of Notre Dame*, and *Mulan*, among others.

A game phenomenon that began in the 1980s and grew to great popularity in the 1990s was the simulation game. Simulation games had grown out of educational games such as *Oregon Trail* (1978) that had been designed to simulate real world activities and provide players with a greater appreciation of the real life events. The success of *The Sims* in 1990 and of *Railroad Tycoon* in 1993 encouraged the development of simulation games for children such as *Harvest Moon* (1997). In this game, children were responsible for allocating their time to best maintain a farm that had fallen in disrepair. They were provided daily tasks to complete, different environments to explore, and, among other things, weather to contend with. Simulation games such as this one were "learning in context," and fit the genre, although were not always labeled, edutainment.

Such a learning simulation game that leads us into the next topic, handhelds, is *Nintendogs* (2005). Handhelds are particularly suited to providing children a means to carry out set tasks in real time. In *Nintendogs*, children take care of their pet dog on the Nintendo DS. Using the touchscreen, they can train their dog, take it to the park, and wash and brush it. They can also record commands that the puppy should obey if it has been trained correctly. A real-time simulation, the action is based in the DS's calendar and clock so, for instance, a puppy would grow hungry if not fed on time; the game provides feedback for acting responsibly toward a pet.

Handhelds Prepare the Way

During the 1980s, handheld games gained tremendous popularity. Small and easily

transportable, they could be used anywhere from the sofa to the car seat; playing video games no longer kept children tied to computers at a desk or console – a large part of handhelds' charm for both children and parents. Introduced at the beginning of a new era, when parents trekked their kids from activity to activity in that other phenomenon of the time, the mini-van, handhelds became a part of children's everyday life and probably more than any other game technology were the determinant of today's generation of digital natives.

Handhelds had their origin in the single game electronic devices of the 1970s, such as *Auto Race* (1976) and *Football* (1977) made by the toy manufacturer Mattel. When Nintendo introduced *Game and Watch* in 1988, a single game format with one small screen and two or four buttons, it had similar simple game action that also challenged skills. The games were both educational and entertaining: *Flagman* (1980) was a memory game in which the character on screen showed a random number the player had to memorize and input into a series of squares. The format's popularity was increased through games that featured well-known cartoon and video game characters such as *Mickey Mouse* (1981), shown in Fig. 9, *Popeye* (1981), *Snoopy* (1982), *Donkey Kong* (1982), and *Mario Bros* (1982), who brought their own background stories as context and backdrop for the games (RolyRetro 2016).

The success of Nintendo's next handheld system, *Game Boy*, introduced in 1989, is based on the popularity of its games rather than in any sophisticated technology. In comparison to its competitors, its green screen was blurry and graphics were unimpressive, yet it became the most successful video game system ever – handheld or otherwise – because of its strong stable of notable games. It was released with what became the most popular game of all time, *Tetris* (Melanson 2006), and then featured a wide spectrum of game genres: puzzle games – *Boxxle (1990),* adventure games – *Who Framed Roger Rabbit* (1991), historic action adventure games – *Prince of Thieves* (1991), sports games – *Ultra Golf* (1992), fighting games –*Street Fighter II* (1995), pinball games – *The Getaway: High Speed II* (1995), racing games – *Street Racer* (1996), and side-scrolling platform games – *Toy Story* (1996).

Children enjoyed playing these games – parents saw their children were not only occupied but were also learning new skills: a win-win situation that helped establish playing handheld games as a go-to activity, one that translated readily to playing games on mobile phones, when that technology became available.

The most recent iteration of mobile gaming that continues children's (and adults') enthrallment with this genre of game play is the Nintendo *Switch* (2017), a hybrid console that can be played on-the-go as a handheld or on a TV at home. It consists of a main unit with Joy-Con controllers attached to each side that can be slid off so the

Children's Games, from Turtle to Squirtle, Fig. 9 In *Game and Watch*, Mickey runs to catch eggs falling from one of four chutes

screen can be propped up on a table for one- or two-player games. The Switch system also includes a charging cradle so games can be played on a big-screen TV. The design allows for players to get the same basic experience regardless of how they play (Thang 2018).

The Internet Introduces Community to Children's Games

At the same time as handhelds were keeping children enthralled in the world of desktop computers, the internet was changing into a user-friendly place that was opening up doors for gaming of a different nature. In 1994, Netscape Navigator brought the graphical user interface to the general public and changed the face of the World Wide Web both for adults and children. At the time, edutainment CD-ROMs were at their height. As children's authors took advantage of the new technology to create edutainment websites such as *Banph, Chateau Meddybemps, Fablevision*, and *Little Critter World-Wide Network* (Fig. 10), based in their own work, the industry faltered and would never again be so financially successful. All of the activities CD-ROMS provided were now available online, if perhaps not quite the same quality, for the cost of a service provider (Madej 2007).

Online access also popularized Massive Multiplayer Online Role-Playing Games (MMORPGs), which, at the time, were considered an adult genre. In 1996, *Starwave Corporation* brought the genre to children 8+ with the game *Castle Infinity*. Entertainment video games had over the years stirred up considerable controversy with addictive and violent game play dominating the discussion; diverse opinions were held about the value of games for children. Multiplayer online games were equally suspect. *Castle Infinity* promoted the use of nonviolent ways of problem solving: how to get rid of monsters who were threatening the last of the dinosaurs in their home, the Castle. Children used a password and a unique name to join players around the world in cooperatively saving the dinosaurs.

Into the fray of concern about online entertainment *The Disney Company* launched an ambitious site for children, *Disney's Daily Blast* (1997). The site offered parents a gated environment in which their children could connect with each other safely. Attractively designed to be child-friendly, the site offered a changing range of stories, comics, arcade games, and educational games for online play, either alone or with chosen friends (Fig. 11). Multiplayer games included the musical activity *Music Room Composer,* in which children could compose and record music, share music with friends who could comment on the composition, and play in jam sessions (Lee and Madej 2012).

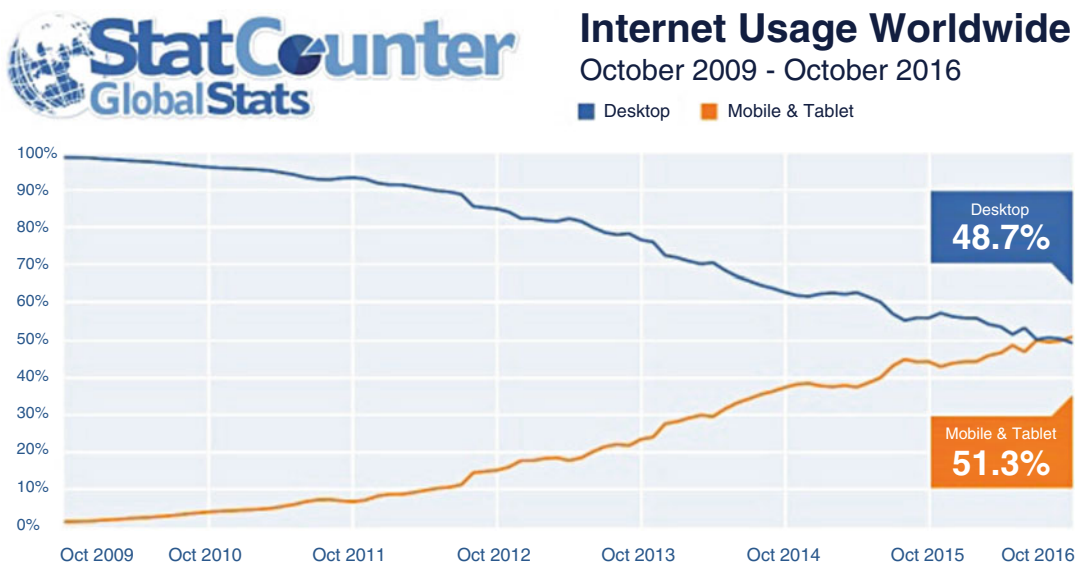
Children's Games, from Turtle to Squirtle, Fig. 11 *Disney's Daily Blast* presented a child-friendly portal page to a gated environment

By the 2000s, the major children's publishers and media companies, from *PBS Kids* to *National Geographic Kids,* realized the promotional opportunities of engaging children online, and created sites that were based in children's favorite characters and stories such as *Arthur, Caillou, Clifford, Dragontales,* and *Sesame Street.* These sites offered learning opportunities through entertainment, although initially they did not offer a multiplayer environment.

Today, many games are available in versions that can be downloaded from the Internet. The sandbox game *Minecraft* (2010), for instance, which is now the second most popular game after *Tetris,* can be purchased for single play or can be played online with friends. A sandbox game is an open-world game akin to playing with *LEGO* blocks and building objects or scenes, only the number of blocks is limitless. In *Minecraft*, children 6+ decide for themselves what to do and how to do it. They collect materials available in the space and build whatever their mind can imagine. As online friends they can cooperate to build worlds together.

Changing Handheld/Mobile Landscapes

Mobile technologies brought the connectivity of the internet to the portable handheld. Tablets replaced desktops and laptop computers for children in many homes. Their small size, portability, relatively low cost, and Wi-Fi connectability made them a practical device for playing favorite games, including online games, anywhere in the home, or indeed, even away from home. The smartphone has quickly replaced even the convenience of the tablet for Wi-Fi access (Fig. 12)



Children's Games, from Turtle to Squirtle, Fig. 12 Up from 2016, shown above, 2017 stats indicate mobile use continues to increase. Mobile – 52.29%, Desktop – 43.29%, Tablet – 4.42%

(Mobile and Tablet Internet Usage 2016). It is useful to parents, engaging for their children, and is ever present. Easy availability and mobility, together with the fact that, like a handheld, a smartphone fits a child's hands well and has a responsive touch screen (tablets have this as well), makes it a most advantageous digital entertainment device for on-the-go parents who want to occupy their children. In addition, game developers have been assiduous in fulfilling parent's requirements for educational games and children's need for entertainment games both for IOS and android tablets.

Mobile games for children, while limited by the speed of the technology and the size of a device's memory, were initially not much different from what children had available to them on a desktop or laptop computer. A traditional edutainment game for mobile devices, *Brain PoP: Today's Featured Movies,* for instance, uses internet connectivity to present a new set of movies each week about topics from math to social science. Children choose their topic and accompanying movie, watch, and then answer a pop quiz. Whether either at the behest of their parents or on their own, children are learning the alphabet, learning coding through puzzles and games, or learning to speak Spanish by saving trapped toys, they have access to hundreds of applications through dozens of websites specifically for learning or identified as just-for-fun (during which learning does go on). An example of a popular (most downloaded game of all times) game is *Angry Birds* (2009). A puzzle, turn-based game for ages 8+ in which cute birds aim to retrieve their eggs from some greedy pigs, it has no new types of interactivity, but does have engaging characters in fun and wacky side-scrolling gameplay (Cheshire 2011). *Angry Birds* has translated well into cross-media activities such as children's library programs and use in early learning environments such as preschools. *Cut the Rope* (2010), in which players must feed a little green creature, Om Nom, with candy they retrieve from hanging ropes, requires more challenging planning and dexterity in use of the touch screen to cut the rope. It is also popular across media so that children have opportunities to transfer their mobile knowledge to physical play (Fig. 13).

Mobile devices have become very popular with parents for very young children as well. Designers have put such technology as the touch screen to great advantage in games for them. In

Children's Games, from Turtle to Squirtle, Fig. 13 Playing *Cut the Rope* on a smartphone requires planning ahead and dexterity. Cross media marketing, for this as for many other games, has provided players with real world artifacts for interacting with Om Nom

Old Macdonald (2009), for instance, young children can use their fingers to push a tractor, open barn doors, jump with frogs, pop balloons, and swish their way through the rhyme as the tune plays to the animations. Together with parents or alone, children can also read, listen, and record themselves singing. This engages them not only cognitively but also physically in their play activity, creating stronger connections in their learning (Madej 2016).

Tangible Games

The most recent developments in tablet and smartphone games, virtual reality (VR), augmented reality (AR), and mixed reality (MR), are at the end of a trajectory of evolution in action video games that, during the mid-1970s, took the form of accessories such as racing wheels, and today, has players moving about the neighborhood, the city, or even the world, searching and catching virtual Pokémon. While manifested in different ways, the main purpose of action games is to provide tangible or embodied interaction that engages the player physically and simulates real world activity. This could be by providing haptic feedback, physically engaging interaction, an immersive environment, or by augmenting an existing environment.

Among the first live-action games were racing games and marksman games. Although entertainment oriented, many of these games required children to improve skills to acquire higher scores or

Children's Games, from Turtle to Squirtle, Fig. 14 The Coleco *Telstar Arcade* (1976) with its racing wheel and pistol

reach new levels of ability. Coleco's *Telstar Arcade* (1976) (Fig. 14) exemplifies early interest in creating a simulated experience for home video games. The three-sided *Telstar* featured two sides that provided for a "real experience." Players controlled a racing wheel while playing racing car games on one side, or drew and fired a pistol for target shooting on another side. On the third side, players used typical game buttons to control pong games such as tennis (Madej 2007). Racing wheels continue to be used and are still bundled with racing games for systems such as *Mario Kart Wii* (2008).

New types of interactive artifacts that engaged children physically were introduced in the late 1990s and early 2000s. These included play

mats on which children could enjoy dancing to the music video game *Dance Dance Revolution* (1998), konga drums they could beat in *Donkey Konga* (2003), and guitar controllers they could strum in *Guitar Hero* (2005). Each of these interfaces required improving skills to reach the next level of proficiency and provided for learning while playing.

While mixed reality appears to be a very recent phenomenon in children's video games, it was first seen in Sony's *EyeToy:Play* in 2003. Sony used an inexpensive webcam to literally put the player into the game through motion capture video. Players could dance, Kung Fu, wash windows, play soccer, or box against themselves. While *EyeToy* caught the imagination, it was difficult to get the actions right to appear on the screen. This difficulty caused frustration. It wasn't until the *Wii* console system, which detected the player's movement in three dimensions, was introduced by Nintendo in 2006 that motion capture gameplay became seamless and enjoyable rather than frustrating. Both Wii arcade games and its narrative games used the technology to advantage. In the medical drama, *Trauma Center: Second Opinion*, the player, as Dr. Derek Stiles, sets broken bones, cleans and stiches wounds, and simulates the use of a defibrillator during an emergency situation: he has to "shove the two controllers forward to shock [the] patient[s]" (Fig. 15) (Trauma Center 2006).

Wii games were promoted for children as young as toddlers and games like *Kirby's Return to Dreamland* were positively viewed as family friendly because of their multiage, cooperative play. But toddlers and preschoolers found the controls difficult, both in this and other games such as *Reader Rabbit Kindergarten* in which any precision was required (Healy 2011). Issues also arose when Microsoft introduced the next motion capture device to come on the market, the *Kinect* (2010). Older children could engage in simulated action in games but problems existed with recognition of younger children because of their height, as well as with light levels, the amount of space required to play, and recognition of movements (Kinect Sucks for Little Kids 2012).

Mixed reality games entered a new era when they began to include either or both VR and AR in their mix. Virtual glasses such as Google Cardboard, a simple, inexpensive version of a VR headset, became an asset in the development of immersive adventures for children. Edutainment benefitted in particular in games such as *Jurassic Virtual Reality* (2014), in which children go back to the time of the dinosaurs and can observe the creatures in their natural habitat from any angle. The ability to engage in a very personal way within an environment makes learning immediate and takes edutainment to a new height.

Children's Games, from Turtle to Squirtle, Fig. 15 Wii *Trauma Center* requires players to simulate real-world action

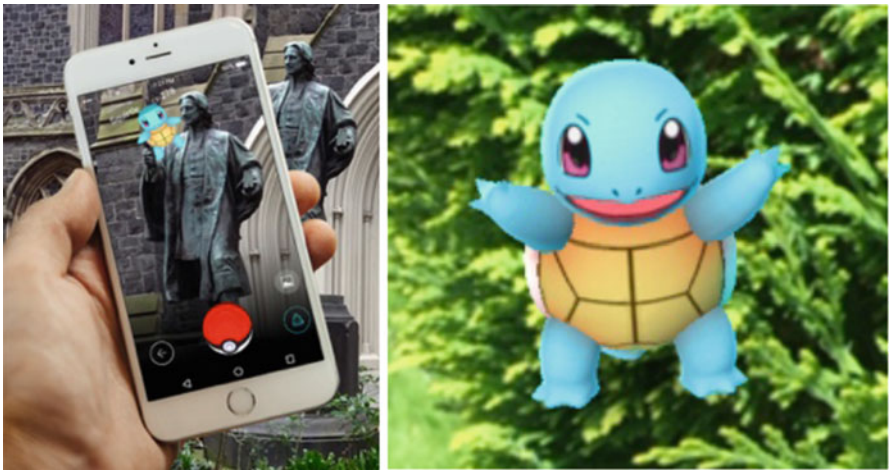
Children's Games, from Turtle to Squirtle, Fig. 16 (**a**) *colAR/Quiver* character, (**b** & **c**) *Toy Car RC*'s Western World brought to life through AR

In September 2013, *colAR Mix*, now called *Quiver*, was announced as an AR coloring experience for children. This application let children bring characters they colored on pages printed from the app to life in 3d when they are viewed through a tablet or mobile phone and added an engaging new experience to traditional coloring (Fig. 16a). Each new MR application seems to raise the bar for engagement: *Toy Car RC* (2014) for children 6–8, follows the adventures of a small car named Wheely that is always searching for an adventure. Once children print out and position target pages in a space, they set Wheely on his journey and connect the real world with a virtual world, either Candy Land or Western World (Fig. 16b, c).

The AR game *Pokémon GO* (July 2016) brings us to the end of the trajectory of action games, at least for our present time frame. It is also where, for the moment, this brief history of games ends. *Pokémon GO* has taken what is the most used platform for games, the smartphone (which we carry with us everywhere), paired it with well-loved and storied characters (which few, if any, of us have not heard of), and simply asks of players that they look around their natural environment to find and collect Pokémon and then share these collections with others. *Pokémon GO* is currently being used for classroom assignments: children "Keep a log of where they go, what they see, and what they are learning as they play, including historic places and points of interest" (Gracey 2017). But a classroom situation isn't needed to spark interest in learning for children who search for Charmander, Bulbasaur, or Squirtle (Fig. 17). While Rolling Stone says *Pokémon GO* is "a free-to-play, location-based, augmented reality, multiplayer online mobile game that also supports its own custom wearable tech" (Davison 2016), more humanistically speaking, and more to the point, through its enthusiastic embrace of engagement with the real world *Pokémon GO* shows how technology, story, and environment can be joined effortlessly to engage us communally in an entertaining game that engages children in learning.

Finally

In 2017, 60 years passed since the *LOGO Turtle* was first introduced to the world. Seymour Papert's interest during the 1960s in creating a playful environment with computer technology to benefit children's learning continues to be pursued with vigor by the games industry today. Through an unflagging continuance of effort, and whether developing games solely either for learning or play, or developing games intended to do both, the different streams that have evolved are exploring technologies as quickly as they are emerging and taking advantage of new types of engagement to offer a mix of learning experiences. While some may not see searching for *Squirtle* as beneficial to learning, others have taken the idea, and exploited its potential to engage a generation of children, many of



Children's Games, from Turtle to Squirtle, Fig. 17 *Pokémon GO*: Searching for *Squirtle*

which, have never been without a digital gadget in their hands.

Classical Learning Method in Digital Games

Youichiro Miyake
Square Enix Co., Ltd., Tokyo, Japan

Synonyms

Genetic algorithm; Machine learning; Neural networks

Definition

Classical learning includes simple neural networks, genetic algorithms, and so on. Few game titles utilize classical learning because these must be harmonized with game design. Thus, the main problem of implementing the classical learning method in digital games is finding out how to synergize a classical learning algorithm and game design.

Introduction

Learning has not always been used in digital games; rather, it is used only in specific and limited contexts. There are two reasons for why the application of learning is limited. First, the game is usually developed on a game design, and it is adjusted to be strict good balance by a game designer's sense. Learning AI method introduces unpredictability and variations. It is considered difficult to combine learning algorithms with game design. To address this, advanced game design technologies that absorb the fluctuations of learning algorithms and engineering technology to safely control learning are both needed. Second, learning requires CPU and memory resources, which sometimes puts heavy load on graphics and other game characteristics. However, the latter is gradually being addressed by improvements

to the computing performance of the game and development machines. Accordingly, learning algorithms are being incorporated gradually into games and game design.

In the 1980s and mid-1990s, when artificial intelligence (AI) technology was used, it almost completely exhausted the memory and CPU resources available for the game. Thus, these were marketed as "AI Games." Some examples include enjoying a conversation with a virtual woman in "Emmy II" (ASCII, 1984), training a puppy in "Puppy Love" (Addison Wesley Publishing), simulating the life of a family in "Little Computer People" (Activision, 1985), and simulating the life of a girl in "Appletown Story" (Square, 1987).

Towards the latter half of the 1990s, the performance of game machines improved reasonably. Accordingly, AI algorithms such as "Genetic Algorithms (GA)," and "Neural Networks (NN)" were gradually incorporated into games. Large-scale neural networks on the order of a few thousand nodes were utilized to allow players to teach creatures "Creatures" (Millennium Interactive, 1996), where the characters in the game were taught to use objects within the game. Moreover, in the PlayStation, AI game masterpieces by Mr. Yukihito Morikawa of muumuu continued to be released (Morikawa 1999). "Ganbare Morikawakun 2gou" (English title: Pet in TV) (muumuu, 1997) was a game for imparting intelligence to "Morikawakun 2gou," where the intelligence in Morikawakun 2gou was inculcated through the learning of instructions from players utilizing a back-propagation neural network. Moreover, in "Astronōka" (muumuu, 1998), the performance of the enemy characters was designed to evolve according to the way the players play by utilizing a GA. In the 1990s, the reverberations of the second AI boom were late in infiltrating the game industry.

In the 2000s, the number of "AI games" gradually reduced with the rapid development of 3D graphics. There was a gap of several years before learning started to be incorporated into specific areas within a game. "Black & White" (Lionhead Studios), which was released in 2001, is a game in which the user leads the inhabitants and make them thrive. Simple neural networks (perceptron, three for input, one for output) are set for the creatures, which learn depending on the discipline enforced by the user (Evans 2002). In this manner, they learn what actions to take depending on the motivation. In the "Forza Motorsport" (Turn 10 Studios, 2005) series, a mechanism called Drivatar was introduced to learn the user's driving technique (Microsoft Research 2014). This was a type of "machine learning" that automatically learned deviations from an ideal racing line set for each course; the learnings were used as a parameter of "steering handling." Moreover, as an example of related research, at Microsoft Research, (2004) the AI in the fighting game "Tao Feng" (Studio Gigante, 2003) was successfully improved by using the Q-Learning method, which is a type of reinforcement learning realized through interactions with players (Herbrich et al. 2008; Graepel et al. 2004).

With respect to targeting (selecting enemies), among the AI techniques, one example of the use of neural networks in the 2010s, is "Supreme Commander 2" (Gas powered Games, 2010) (Robbins 2013). It learns which enemy to target around the character, from approximately 60 min of play by the developer, by using back-propagation. Moreover, in "Killer Instinct" (Rare Ltd., Iron Galaxy Studio, 2014), the case-based reasoning method is adopted, where AI play is set up by using play data from users (Hayles 2015). Moreover, although its development was cancelled, in "Fable Legends," Monte Carlo Tree Search (MTCS) was used to locate the positions of enemy groups (Mountain 2015) (Fig. 1).

Thus far, some examples of the application of evolutionary learning algorithms have been described; however, the reality is that, until 2018, the number of "cases of clear application to a game" was very small. Although the application to games is described in the next section,

Year	Title	Method
1996	Creatures (Mullennium Interactive)	Neural Network
1997	Ganbare Morikawakun 2Gou (muumuu)	Neural Network
1998	Astronoka (muumuu)	Genetic Algorithm
2004	Tao Feng (Studio Gigante)	Q-Learning (Reinforcement Learning)
2005	Forza Motorsports (Turn 10 Studios)	Machine Learning (Statistical Learning)
2010	Supreme Commanders 2 (Gas powered Games)	Neural Network
2014	Killer Instinct (Rare Ltd. Iron Galaxy Studi)	Case-Based Reasoning
2015	Fable Legends (Lionhead Studio)	Monte-Carlo Tree Search

Classical Learning Method in Digital Games, Fig. 1 Examples of the application of learning and evolutionary algorithms to games (main unit)

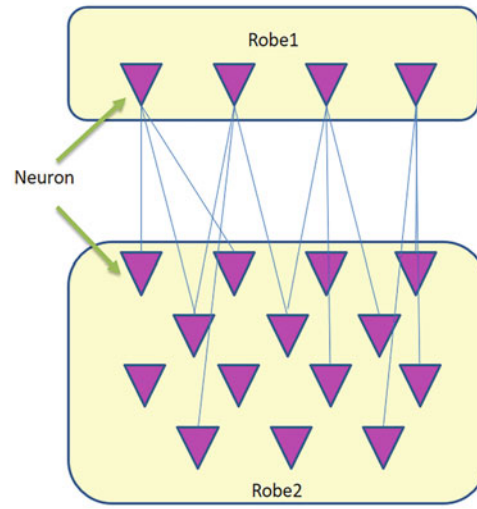
there is a rapidly increasing trend. Even though the performance of game machines continues to increase, the problem regarding where this should be incorporated in the game design still remains a formidable challenge. We discuss each of the cases.

Neural Network in "Creatures"

Because "Creatures" (Millennium Interactive Ltd, 1996) is a game for personal computers that was released in the 1990s, it is not well known in Japan; however, it is well known internationally, and has been highly evaluated, winning many awards. It is a game in which creatures called "Norn" are raised, and in particular, they can learn language as well as the names of the objects and actions inside the game. Once learning is complete, simply by providing a word, they can be made to perform the corresponding specific action.

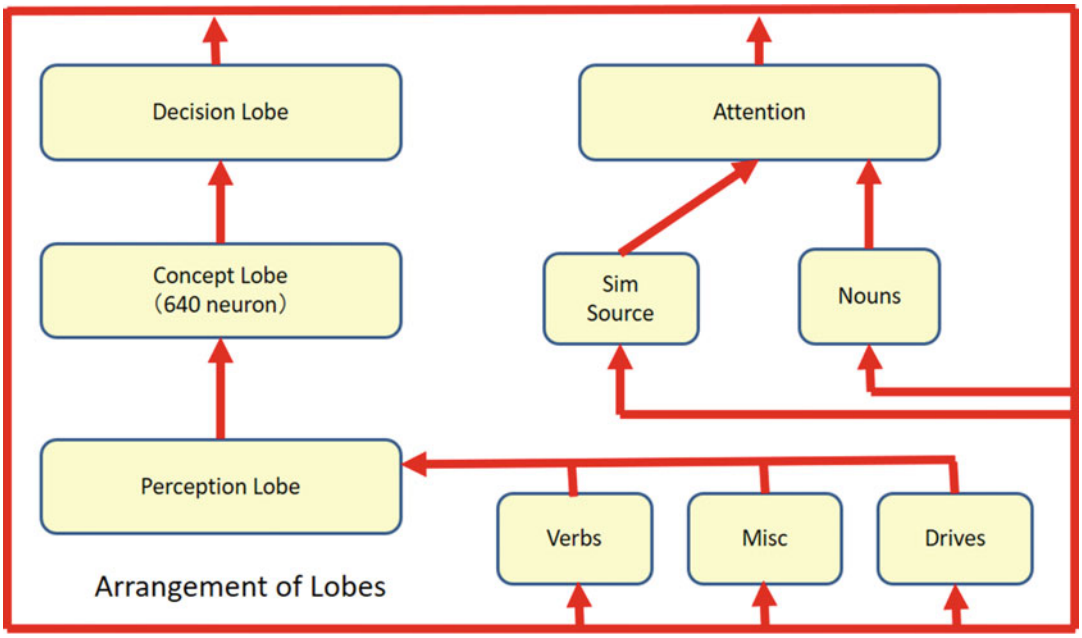
At that time, the brain of a Norn consisted of a neural network comprising a few thousand nodes. A set of neurons is called a "lobe," and neurons in each individual lobe are interconnected with neurons in other lobes (Grand and Cliff 1997) (Fig. 2).

The intelligence of Norn is based on the agent architecture. The sensory lobe senses external signals. For example, when a ball is seen, the neurons responding to the ball become active. The user shows various objects to the



Classical Learning Method in Digital Games, Fig. 2 Unit of Norn brain "Robe"

Norn, upon which the attention lobe responds. The Norn then says the name of the target object (noun) or the action (verb) corresponding to the behavior. The user by using a mouse gently caresses the Norn when a correct answer is provided or slaps it when the answer is incorrect. In this manner, the neurons in the neural network learn the nouns and verbs used in the game. The users can also enter the words. The neural network learns by matching the target with the word, or the action with the word (see Fig. 3).



Classical Learning Method in Digital Games, Fig. 3 Schematic of lobe (neural network) in "Creatures" (Grand et al. 1996)

Learning and Evolutionary Algorithms in Japanese Game Scenes in the 1990s

The second AI boom is said to have occurred during 1984–1994. Accordingly, its effect was still observed in the latter half of the 1990s. In the gaming industry, in the late 1990s, with a slight delay, various games using AI were released. "Creatures" was one such game. In the Japanese gaming industry, two games using AI were released in the late 1990s, "Astronōka" and "Seaman" (SEGA, 1999). Yukihito Morikwa developed the former, and Yutaka Saito developed the latter game. The characteristic of AI used in the games during this time was that AI attributed to a large proportion of the total content since a large portion of the resources needed to be allocated to AI. This implies that other elements such as game design and CG were closely intertwined with AI. In such games, a game creator was required to design the game consistently, from the game design to the technology adopted. Both Morikawa and Saito undertook such a design process to integrate the game design with AI.

Learning algorithms were incorporated into a series of AI games created by Morikawa:

Back-propagation neural network in "Ganbare Morikawakun 2gou" (SIE, 1997)

Genetic algorithm in "Astronōka" (SQUARE ENIX, 1998)

Back-propagation neural network in "Kokohore! Pukka" (English title: Dig a-Dig Pukka) (SIE, 2000)

Autonomous lyric generation in "Kumauta" (SIE, 2003)

In "Ganbare Morikawakun 2gou," specifying a behavior (action) corresponding to an object discovered by a character, enables it to undertake appropriate behavior corresponding to the sense of perception of the character about the target object. In "Kokohore! Bukka," the player teaches the agent the type of stones to be dug out through a reward system, the agent gradually starts judging the stones by itself. In "Kumauta," the agent autonomously creates lyrics corresponding to the lyrics selected by the user, which the white bear then sings in the enka style.

A short introduction to "Astronōka," where a genetic algorithm is used, is given below.

Genetic Algorithm in "Astronōka"

"Astronōka" uses a genetic algorithm to help the enemy characters evolve. The players cultivate vegetables and set "traps" in the field to exterminate pest characters called "baboo" that harm the vegetables. The "traps" are regions divided into a grid-like mesh, where players can place fans, scarecrows, or pitfalls to trap the pests.

In the latter half of the 1990s, the media reported on the vicious cycle of "the spraying of pesticides, followed by the increase in the pests' resistance to the pesticides, and further spraying of the pesticides" in Yumenoshima in the Tokyo Bay. This game was inspired by this incident. That is, in the game, the stronger the "trap" set by the users, the more the "baboo" evolves.

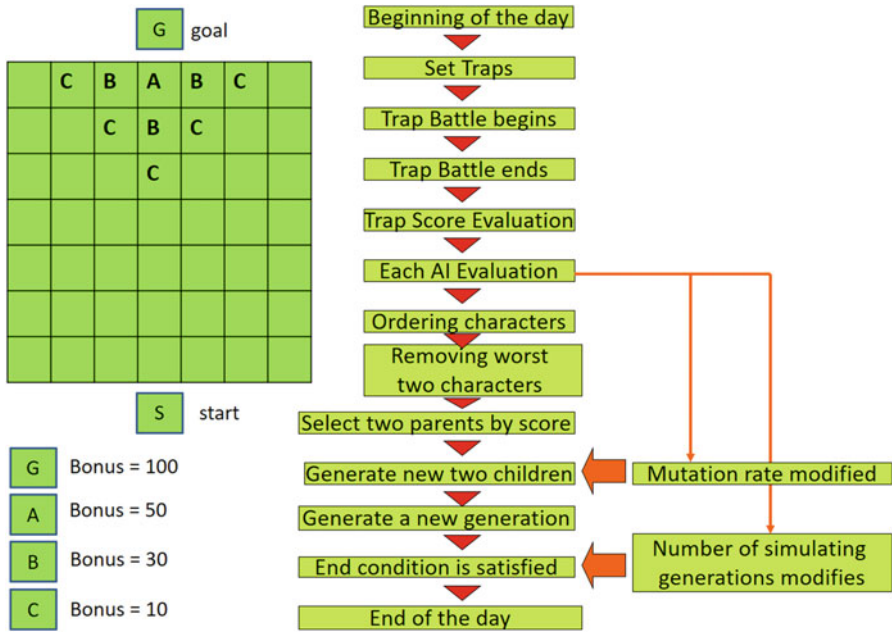
Each character has a parameter column that determines the performance of the character. The parameter column comprises 56 kinds of items, such as physical fitness, endurance, arm strength, leg strength, and resistance to various traps (Morikawa 1999).

Each baboo challenges the traps, and the result is given as a score; baboos with higher scores are selected so that they become parents with high probability based on their superior adaptability and pass their genes to the next generation. Their mutation rate is set to 3% (Fig. 4).

While on the surface it appears that among the 20 baboo characters in the game, each character is challenging the trap only once, in the background, simulations are carried out for all the 20 baboo characters evolving over five generations; this mechanism can only be implemented in a game. This is done to make the users believe in the evolution of the enemy. If the rate of evolution is low, more generations are added, and conversely, if the rate of evolution is high, the number of generational changes are reduced.

Study on Machine Learning at Microsoft Research

In the game industry, the third AI boom took place after 2015, although research on the application of



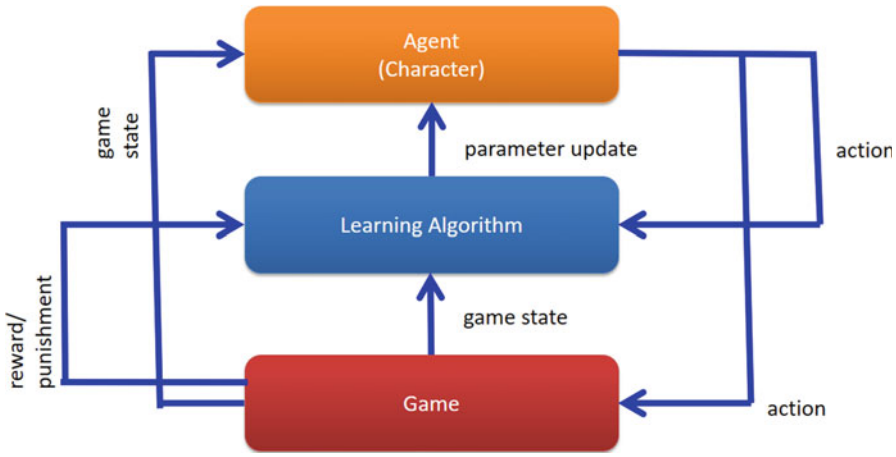
Classical Learning Method in Digital Games, Fig. 4 Genetic algorithm mechanism in "Astronōka"

ML in games has proliferated, Microsoft Research, from as early as 2004, was engaged in research on ML in digital games. The success of this research is exemplified in "Forza Motorsports" and various papers. As mentioned earlier, before 2004, a group in Microsoft Research studied the fighting game "Tao Feng" (Microsoft, Studio Gigante, 2003). They studied the reinforcement learning of characters (Herbrich et al. 2008; Graepel et al. 2004). Reinforcement learning is an algorithm to learn from experience. Instead of any clear teaching signals, rewards are set with respect to the orientation of learning that enable the agent to learn actions from the surrounding environment in accordance with the rewards. Two types of rewards have been used in fighting games. The first is rewarded when an attack hits the opposing character (reducing the opponent's physical strength). In such a reward system, reinforcement is realized through repeatedly learning the skills to use in a particular situation. As a consequence, a character that has undergone reinforced learning through tens of such engagements will become a "strong" character. Conversely, the reward is provided when the character is able to skillfully dodge an attack from the enemy. Consequently, the character after undergoing reinforced learning through tens of such engagements will become a "fleeing" character. This way, a character can be taught through reinforcement learning, and the orientation of such learning is determined by the rewards. In particular, Q-learning, which is an algorithm for reinforcement learning, was used in this study. Q-learning is suitable for continuous reinforcement learning with temporal transitions, and it is frequently applied to learning in digital games.

Machine Learning in Forza Motorsports Series

In Forza Motorsports, a player called "Drivatar" has the ability to learn driving skills and generate ghosts to drive. First, the course in Forza Motorsports is divided into segments. The segments can be straight or hairpin-shaped. An ideal course is set for each such segment. Then, the deviations from these specified courses are measured (Herbrich et al. 2008) (Fig. 5).

Next, to reproduce the deviations as a ghost, they are reverse transformed and reflected in the controller operation to reproduce the previously measured deviations. Instead of forcing the car to follow the externally specified course, it is reduced to a reverse problem, where the car attempts to reproduce the course "just as the user had deviated."



Classical Learning Method in Digital Games, Fig. 5 Reinforcement learning algorithm (Herbrich et al. 2008)

Case-Based Reasoning in Killer Instinct

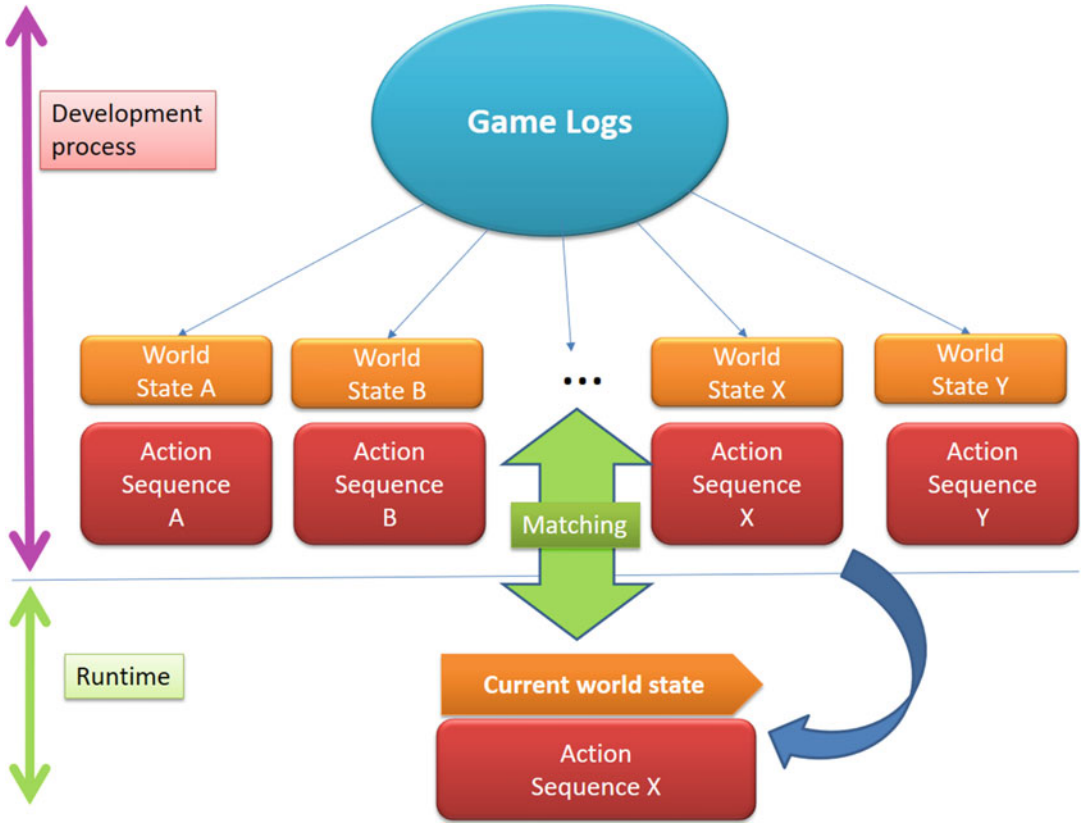
"Case-based reasoning" (CBR) is an algorithm for obtaining a solution to the problem under consideration from the recollections of similar cases in the past. Although a few studies on the application of CBR to digital games have been reported, very few actually adopted them (Aha et al. 2005).

"Killer Instinct" (Rare Ltd., Microsoft Corp., 1994–2016), created "Shadow" that grows through learning the fighting and style of players from past data (Hayles 2015). By accumulating game logs and using the concept of abstract distance, multi-dimensional and large-dimensional data are vectorized into "Game State," and the most effective action corresponding to each such state is extracted. When the game is played, the Shadow searches such data for the action most appropriate for a specific situation (Fig. 6).

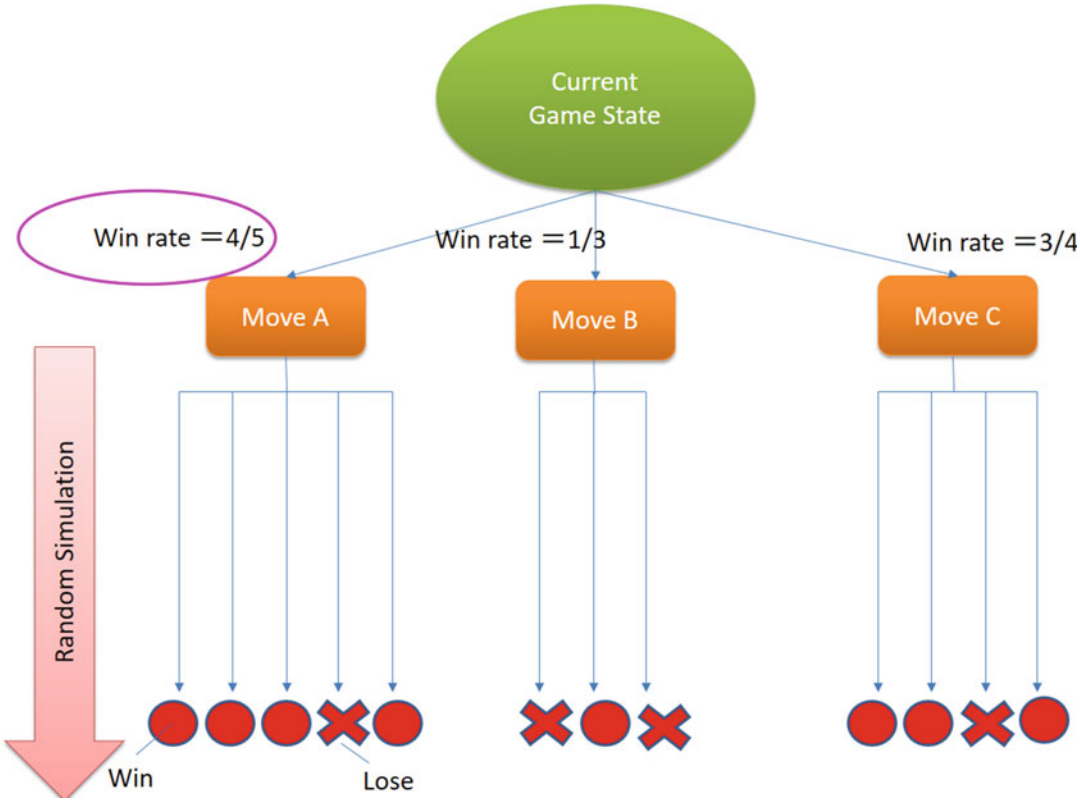
Monte Carlo Tree Search in TOTAL WAR

Monte Carlo Tree Search (MCTS) is a revolutionary and powerful method that was invented for the computer Go program. Simulation is the primary approach in this method. Further, as it requires no evaluation, it is very useful in game development. Hence, many related studies have been conducted on its application to computer games (Fig. 7).

When there are multiple candidate moves, the MCTS algorithm performs random simulation of all possible moves of the game beyond that point and selects one after evaluating the win–loss status of all such moves. Moreover, the number of simulations is increased for promising moves, to generate an index called upper confidence bound (UCB), which is the cornerstone of this algorithm.



Classical Learning Method in Digital Games, Fig. 6 Case-based learning principle



Classical Learning Method in Digital Games, Fig. 7 Monte Carlo Tree Search Method

MCTS has superior applicability to simulation games and has been used for adjustments in the campaign mode (single-user mode including tutorials) in "TOTAL WAR: ROME II" (Creative Assembly, 2013) and "Total War: Attila" (Creative Assembly, 2015) (Champandard 2014). It enables the measurement of the effectiveness of AI strategy by repeating the playouts until the end.

There are three levels in the decision-making by AI when playing "TOTAL WAR":

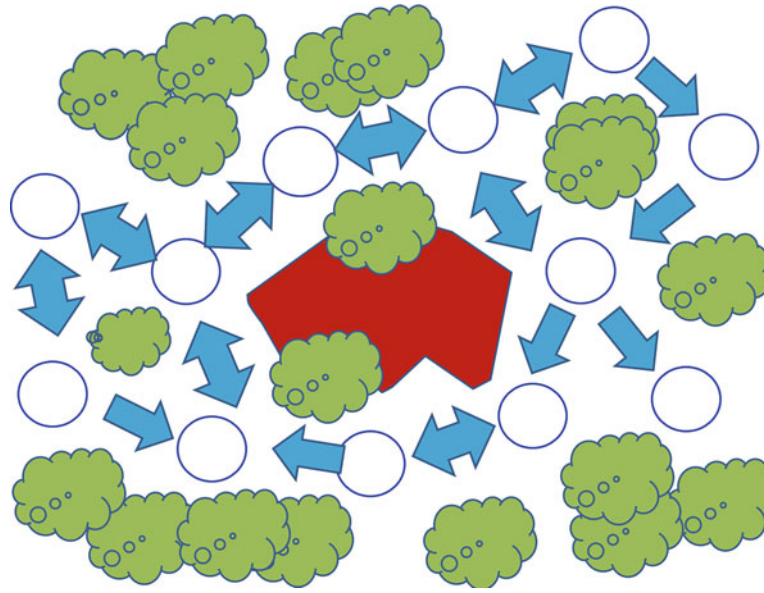
Task creation Set a number of high-level tasks (these do not use MCTS)

Resource allocation Limited resources are allocated to tasks (use MCTS)

Resource assignment MCTS-based decision planner determines the sequence of actions

In this manner, once the AI playing "TOTAL WAR" is developed, it can be made to play many games very rapidly by issuing thousands of commands instantly. Accordingly, it enables the verification of game balance at a very high speed without human intervention.

Moreover, in "Fable Legends" (Lionhead Studios, was not released), MCTS was used to decide the advance of multiple characters (Mountain 2015). Assuming each position as a node, a tree structure that comprised the choices of actions at the respective nodes was considered (Fig. 8).



Classical Learning Method in Digital Games, Fig. 8 Monte Carlo Tree Search in action games

Client/Server Gaming Architectures

Stefano Ferretti and Gabriele D'Angelo
Department of Computer Science and Engineering, University of Bologna, Bologna, Italy

Synonyms

Centralized architectures

Definitions

Client/server gaming architecture refers to a typical distributed architecture for the support of networked games. In this architecture, a single node plays the role of the server, i.e., it maintains the game state and communicates with all other nodes (the clients). The server notifies game moves generated by players and computes the game state updates.

Online Gaming Architectures

An online gaming architecture is typically composed of two types of entities: client entities (CEs) and game state server entities (GSSEs). A CE is a client software application that performs input/output with its player and receives/notifies events to the GSSE to which it is connected. Stated simply, a CE acts as a viewport to the game state and passes commands issued by its player to the GSSE. The GSSE computes the advancements of the game state.

Client/Server Architecture

The client/server architecture is the classic solution used in commercial game products, e.g., Quake, Ultima Online, and Minecraft (Briceño et al. 2014). In this case, a single copy of the game state is maintained at the server-side. Each event generated by a CE is sent to the single GSSE that processes the event computing a new game state; then, the GSSE forwards the newly computed game state to all other CEs. During the game, the GSSE controls the generated events' validity.

In this scenario, clients are very simple since they have only to take inputs from the players and render the output state. Consistency is easy to maintain as well as cheating avoidance, because only a single GSSE maintains the game state, and thus a single node is in charge of determining the game state advancements. For this reason, provided that the GSSE is a trusted entity, illegal manipulations of the game state are extremely difficult/easily detected (Ferretti 2008; Mauve et al. 2002). Often, these advantages push game middleware providers to adopt this architectural solution (Bauer et al. 2004).

However, the major drawback of such an approach is that a centralized server could be the bottleneck of the system (Briceño et al. 2014); moreover, the GSSE is a single point of failure. Furthermore, this architecture is not scalable with the number of players (Reis Cecin et al. 2004). Finally, users that experience different network delays, due to their (possibly) different types of connections, are treated unfairly.

Despite these clear drawbacks, this solution is the preferred one in commercial networked games. This is due to several reasons. First is the already mentioned ease of management of the game state and game administration. Second, when the server is maintained by the game distributors, the server acts as an authoritative control node. In the pay-to-play business model, the server permits to control the access to the gaming servers and to reduce (or avoid) the game piracy. Moreover, this allows to profile users and offer additional services related to the game. An example is in-game stores in which gamers can purchase items and services. In the

last years, many online game distributors have switched to a free-to-play business model in which players have access to a significant portion of their content without paying. In this case, the presence of in-game stores is a key part of the business model. Third, today's games allow users with the possibility of connecting to the game using very diverse terminals and modalities of interaction. In this case, a dedicated server can provide each specific user with different output modalities, based on his/her specific needs. An emerging trend in online gaming architectures is multiplayer browser games in which the game is played over the Internet using a web browser. In this case, the client/server approach is now the most appropriate solution even if new technical solutions (e.g., WebRTC) could permit the development of peer-to-peer browser games.

The client/server gaming architecture can be naturally deployed over cloud computing infrastructures (Marzolla et al. 2012). Multiple servers can be hosted in the cloud, which are devoted to handle different gaming sessions. Such an approach increases the scalability of the provided game service. Moreover, in massively multiplayer online games, the game world can simulate a vast area. In these cases, the game state can be partitioned and distributed over multiple servers. Each server handles a specific portion of the game world and interacts with those CEs that are within that area. According to this approach, once a player leaves the area managed by a given server and enters another area (handled by a different server), it must disconnect from the previous server and open a novel connection with the newer server, all that without introducing consistency errors or affecting the gaming experience of the players.

Cloud gaming infrastructure; Gaming as a service (GaaS)

Definition

Cloud for Gaming refers to the use of cloud computing technologies to build large-scale gaming infrastructures, with the goal of improving scalability and responsiveness, improve the user's experience, and enable new business models.

What Is Cloud Computing?

Cloud computing is a service model where the provider offers computation and storage resources to customers on a "pay-as-you-go" basis (Mell and Grance 2011). The essential features of a cloud computing environment are:

On-demand self-service: the ability to provide computing capabilities (e.g., CPU time, network storage) dynamically, as needed, without human intervention.

Broad network access: resources can be accessed through the network by client platforms using standard mechanisms and protocols.

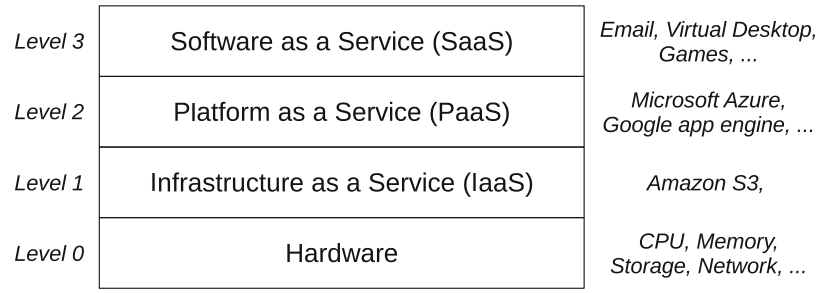
Resource pooling: virtual and physical resources can be pooled and assigned dynamically to consumers, according to their demand, using a multitenant model.

Elasticity: from the customers' point of view, the provider offers unlimited resources that can be purchased in any quantity at any time.

Measured service: cloud resource and service usages are optimized through a pay-per-use business model and are monitored, controlled, and reported transparently to both their customer and provider.

The typical interaction between cloud provider and customer works as follows: the customer connects to a "cloud marketplace" through a Web interface and selects the type and amount of the resources she needs (e.g., some virtual servers with given number of CPU cores, memory, and disk space). The resources are allocated from a large pool that is physically hosted on some big datacenter managed by the cloud provider. Once instantiated, the resources are accessed by the customer through the network. Additional resources can be acquired at a later time, e.g., to cope with an increase of the workload, and released when no longer needed. The customer pays a price that depends on the type and amount of resources requested (e.g., CPU core speed, memory size, disk space) and on the duration of their usage.

The *service model* defines the level of abstraction at which the cloud infrastructure provides service (Fig. 1). In a *Software as a Service* (SaaS) cloud, the system provides application services running in the cloud. "Google Apps" is an example of a widely used SaaS cloud. In contrast, the capabilities provided by a *Platform as a Service* (PaaS) cloud consist of programming languages, tools, and a hosting environment for applications developed by the customer. The difference between the SaaS and PaaS models is that while the user of a SaaS cloud simply utilizes an application that runs in the cloud, the user of a PaaS cloud develops an application that can be executed in the cloud and made available to service customers; the application development is carried out using libraries, APIs, and tools possibly offered by some other company. Examples of PaaS solutions are App Engine by Google, Force.com from Salesforce, Microsoft's Azure, and Amazon's Elastic Beanstalk. Finally, an *Infrastructure as a Service* (IaaS) cloud provides its customers with fundamental computing



Cloud for Gaming, Fig. 1 Cloud service model

capabilities such as processing, storage, and networks where the customer can run arbitrary software, including operating systems and applications. The number of companies offering such kind of services is continually growing, one of the earliest being Amazon with its EC2 platform.

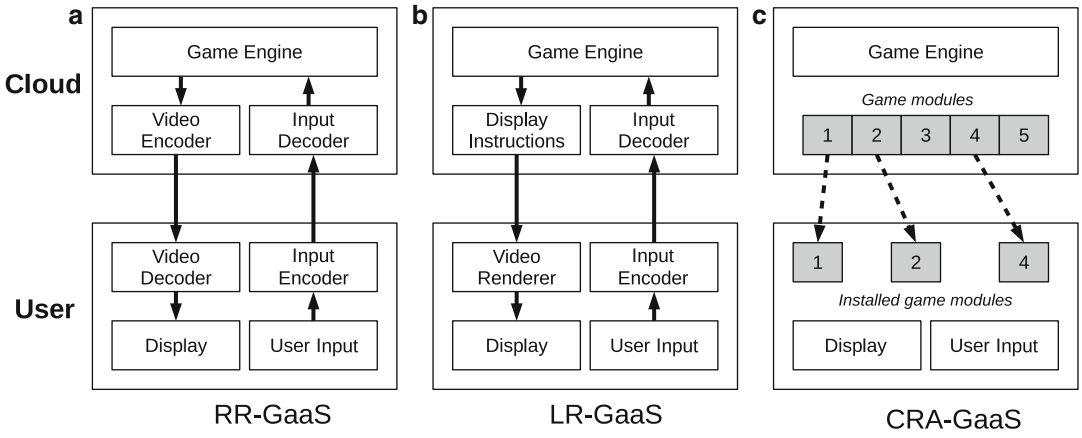
The *deployment model* defines the mode of operation of a cloud infrastructure; these are the private cloud, the community cloud, the public cloud, and the hybrid cloud models. A *private cloud* is operated exclusively for a customer organization; it is not necessarily managed by that organization. In the *community cloud* model, the infrastructure is shared by several organizations and supports a specific community with common concerns (e.g., security requirements, policy enforcement). In the *public cloud* model, the infrastructure is made available to the general public and is owned by an organization selling cloud services. Finally, the *hybrid cloud* model refers to cloud infrastructures constructed out of two or more private, public, or community clouds.

Cloud Computing for Gaming

The gaming industry embraced the cloud computing paradigm by implementing the *Gaming as a Service* (GaaS) model (Cai et al. 2014). Different instances of the GaaS paradigm have been proposed: *remote rendering GaaS*, *local rendering GaaS*, and *cognitive resource allocation GaaS*.

In the *remote rendering* GaaS (RR-GaaS) model, the cloud infrastructure hosts one instance of the game engine for each player (Fig. 2a). An encoder module running on the cloud is responsible for rendering every frame of the game scene and compressing the video stream so that it can be transmitted to the user's terminal where the stream is decoded and displayed. User inputs are acquired from the terminal and sent back to the game engine that takes care of updating the game state accordingly. The advantage of the RR-GaaS model is that the workload on the terminal is greatly reduced, since the computationally demanding step of rendering the game scenes is entirely offloaded to the cloud. This allows complex games to be played on less powerful devices, such as mobile phones or cheap game consoles, that are only required to be capable of decoding the video stream in real time. However, the RR-GaaS model consumes considerable bandwidth to transmit the compressed video stream and may be particularly sensitive to network delays. Examples of RR-GaaS implementations are GamingAnywhere (Huang et al. 2014) and Nvidia GRID™ (http://www.nvidia.com/object/cloud-gaming.html, Accessed on 2015/4/4).

In the *local rendering* GaaS model, the video stream is encoded on the cloud as a sequence of high-level rendering instructions that are streamed to the player terminal (Fig. 2b); the terminal decodes and executes the instructions to draw each frame. Since encoding of each frame as a sequence of drawing instructions is often more space-efficient than compressing the resulting bitmap, the LR-GaaS model may require less network bandwidth than RR-GaaS and therefore eliminate the need for real-time video transmission capability. This comes at the cost of requiring a more powerful terminal with an adequate graphics subsystem.



Cloud for Gaming, Fig. 2 Gaming as a Service models

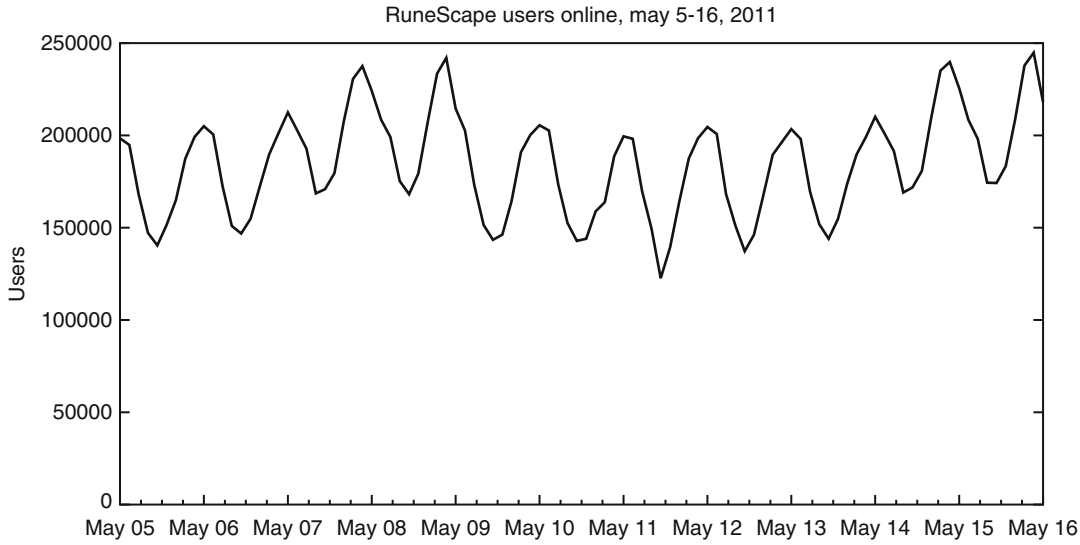
Finally, in the *cognitive resource allocation* GaaS model, the game engine is logically partitioned into a set of modules that can be uploaded and executed at the client side (Fig. 2c). As the game evolves, the terminal receives and executes the appropriate modules and may keep or discard the unused ones. The CRA-GaaS model shifts the computation back to the client terminal, therefore reducing the load on the cloud. However, the client resources are used efficiently, since at any time only the needed components are stored locally. This is a significant advantage if we consider that the data of a complete modern game takes a lot of space for textures, 3D models, sounds, and code modules.

GaaS provides advantages for both game developers and players. The ability to offload some computation on the cloud allows simple terminals such as mobile devices to play complex games. Since the game engine is accessed on demand, flexible business models such as pay-per-play or monthly subscription can be easily implemented. Finally, game operators can scale up and down the amount of cloud resources used by the gaming infrastructure.

The last point is particularly important, especially for the so-called Massively Multiplayer Online Games (MMOGs). Modern MMOGs are large-scale distributed systems serving millions of concurrent users which interact in real time with a large, dynamic virtual world. The number of users playing the game at any given time follows a pattern that originates from the typical daily human activity. As an example, Fig. 3 shows the number of online players of RuneScape (http://www.runescape.com) (Marzolla et al. 2012), a fantasy game where players can travel across a fictional medieval realm. During the observed period, more than 200,000 players are connected to the system at peak hours; this number reduces to about 110,000 players during off-peak hours. Hence, the daily churn (number of players leaving/joining the system during the day) is about 100,000 users. It is evident that static resource provisioning based on the average load results in system overload roughly half the time; provisioning for the worst case results in a massive resource underutilization.

To effectively implement a cloud-based gaming infrastructure, it is necessary to address nontrivial issues related to game state partitioning, responsiveness, synchronization, and security.

Partitioning The key factor for achieving scalability of a GaaS infrastructure is the ability to partition the workload across the cloud resources. This is relatively easy if the workload consists of the execution of independent game instances that can be executed on any available resource, irrespective of where other instances are running. This is the case when the game does not allow different players to interact. Things become complex if the instances are *not* independent, as in the case of a MMOG system where all players interact with the same virtual world. In this case, the game



Cloud for Gaming, Fig. 3 Number of online players of the RuneScape MMOG; the data refers to the period from May 5 to May 16, 2011

engine must maintain a large shared state, allowing the players to "see" the effects of actions performed by the other players operating in the same virtual location.

This is achieved by partitioning the virtual world across multiple zones, each handled by a separate set of cloud resources. Given that communication between resource instances may incur significant delays, it is important that interaction across neighboring zones is minimized. For example, each partition may hold a collection of "islands" such that all interactions happen within the collection, while players can jump from one "island" to another.

Depending on the (virtual) mobility pattern of each player, some areas of the game field may become crowded, while others may become less populated. In order to cope with this variability, each zone controller is physically hosted on resources provided and operated by a cloud infrastructure. The cloud provider is in general a separate entity providing computational and storage resources to the game operator on a pay-as-you-go model. This means that the game operator can request additional servers and/or additional storage space at any time and release them when no longer needed. Thus, the game operator can request more resources when the workload on a zone increases, in order to keep the response time perceived by players below a predefined maximum threshold. When the workload decreases, the game operator can release surplus resources in order to reduce costs.

Synchronization The success of a gaming system is based on having players perceiving the game state as identical and simultaneously evolving on every player participating to a gaming session. If the game state is replicated in different cloud servers, a synchronization algorithm is needed to maintain the consistency of the redundant game state. To this aim, different schemes have been proposed in the literature (Game event synchronization 2006). They mainly differ from classic synchronization algorithms employed by distributed systems in their additional requirement for keeping the computation quick and responsive. To this aim, some schemes relax the requirements for full consistency during the game state computation.

A basic distinction is between conservative and optimistic synchronization. Conservative synchronization approaches allow the processing of game updates only when it is consistency-safe to do so. Lockstep (Fujimoto 1999), time-bucket synchronization (Fujimoto 1999), and

interactivity restoring (Ferretti 2014) are some examples in the literature.

Optimistic synchronization mechanisms process game updates as soon as they receive them, thus increasing the responsiveness of the system. Yet, it is assumed that most updates are received in the correct order and that, in any case, it would be acceptable to recover later from possible inconsistencies.

Examples of optimistic approaches available in the scientific literature are the optimistic bucket synchronization (Diot and Gautier 1999), the combination of local lag and time warp proposed in Mauve et al. (2002), the trailing state synchronization (Cronin et al. 2002), and the improved time warp equipped with the dropping scheme and a correlation-based delivery control approach (Ferretti 2014).

Responsiveness The task of providing a pleasant experience to players becomes challenging when trying to deploy a large-scale and highly interactive online game. Responsiveness means having small delays between the generation of a game update at a given player and the time at which all other players perceive such update. How much such delays must be small depends on the type of online game. Obviously, the shorter the delay, the better. But it is possible to identify a game-specific responsiveness threshold T_r that represents the maximum delay allowable before providing a game update to players. The typical T_r for fast-paced games (e.g., first-person shooter, racing vehicles) is 150–200 ms, but this value can be increased to seconds in slow-paced games (e.g., strategic, role-playing games) (Ferretti 2014; Pantel and Wolf 2002).

A key point is that each player is geographically distributed. Thus, his latency to reach the game server on the cloud is usually different from other players. If a classic client-server approach is employed, it might thus happen that a responsive service is provided to some subset of users, while the other players can perceive a nonresponsive game evolution. This raises another main issue, i.e., fairness provision. This means guaranteeing that all players have the same chance of winning, regardless of their subjective network conditions (Ferretti 2014). To this aim, it should be guaranteed that all players perceive the same and simultaneous game evolution at the same time.

GaaS infrastructures represent an effective tool to provide responsive and fair gaming experiences. Cloud servers can manage the game state evolution in a scalable manner. Multiple server instances can be run in the same datacenter, when needed. Moreover, if the game involves worldwide distributed players, one might think to introduce a federation of cloud servers, geographically distributed, so that each client/player might connect to its nearest server. This could balance the network delays between the player and its server, thus augmenting the fairness level provided by the system. However, when multiple servers are involved, each one with a redundant copy of the game state, synchronization algorithm is needed to maintain game state consistency.

Security and reliability The security issues of GaaS infrastructures have become mainstream after the PlayStation Network outage that, in 2011, has halted the Sony online gaming network for 23 days. The network was shut down after detecting an external intrusion that led to a huge number of accounts being compromised and the exposure of the players' personal information.

From the reliability point of view, large cloud systems provide some level of redundancy to cope with failures, including the use of geographically distributed datacenters, so that catastrophic events do not cause a complete outage. Unfortunately, the GaaS infrastructure may still represent a single point of failure; the PlayStation Network outage is just one example: in that case a security incident prompted the system administrators to temporarily shut down the whole service. Other possibilities must be considered as well: for example, the company operating the GaaS infrastructure may go bankrupt, depriving all players from the game service they might already have paid for.

From the security point of view, GaaS infrastructures are affected by the typical issues of cloud computing (e.g., insider attacks; Zissis and Lekkas 2012) and online gaming (e.g., cheating; Hu and Zambetta 2008). Online games are an appealing target for hacks because players often invest huge amount of time in their character

development, and it is therefore quite easy to monetize game items on the black market. Additionally, individual accounts on online gaming platforms often contain information, such as credit card numbers, that are the typical target of cybercriminals. Details of the avatar of each player can provide information such as sexual preferences (Huh and Williams 2010) that could cause considerable embarrassment if made public.

Information visualization

Definition

Information visualization is the use of computer supported, interactive, visual representations of abstract data to amplify cognition (Card et al. 1999).

Introduction

Information visualizations turn raw data into information and enable researchers to gain insight from the data. Understanding how viewers interpret different types of visual information contributes to the creation of effective and intuitive visualizations. This paper introduces the cognitive processing of visualizations from the angles of pre-attentive processing, visual working memory, cognitive load, and sensemaking. The hope is that this will provide readers enough of an understanding of visualization through visual perception and cognition theories and methods. We presented two case studies that illustrated how cognitive theories inform and impact our research.

State of the Art Work

Vision's Constructive Power

Gardner (1983) advocated for a multiple intelligence theory in 1983 that has drawn the attention of researchers due to its premise that each individual difference's intelligence is composed of multiple intelligences. The intelligences are independent and have their own operating systems within the brain. People with higher visual and spatial intelligences respond better to visual cues by storing, manipulating, and recreating visual information. The constructive power of human vision has drawn the attention of researchers for many years. This section reviews the work of Hoffman, Gombrich, and Arnheim in the domain of visual intelligence and discusses how they inform, impact, and relate the creation and viewer interpretation of information visualizations.

Hoffman and Vision's Constructive Power

Hoffman (2000) attempted to explain the complex mental construction process of all sighted individuals. In Visual Intelligence (Hoffman 2000), he introduced sets of universal and specialized rules that govern our perception of line, color, form, depth, and motion. Hoffman's rule of generic views and 10 rules of visual intelligence clearly explain how individuals interpret and construct visual objects. These rules indicate how our mind organizes data and turn data into knowledge. They can be widely applied to visualization design. People have countless interpretations of what they see, but humans prefer to perceive things quickly and efficiently. The generic views rule is that designers should construct a stable view and a constant image. If an object has more salient-part boundaries, humans will see it as a figure because it is more efficient for our

perception to process clearer evidence and a stronger boundary. Havre et al. (2000) were inspired by the perceptual processes of identifying curves and silhouettes, recognizing parts, and grouping them together into objects. They created a novel visualization tool called ThemeRiver that employs the river metaphor to depict thematic variations over time. Temporal thematic changes can be easily recognized because the system uses smooth and continuous curves to bound a theme and distinct colors to differentiate themes.

Moreover, Hoffman (2000) found that if two visual structures have a non-accidental relation, a designer should group and assign them to a common origin. He also stated that if three or more curves intersected at a common point in an image, they should be interpreted as intersecting at a common point in space. These rules can guide the design of movement data through grouping and stack trajectories based on time proximity and visual similarity. Crnovrsanin et al. (2009) plotted trace as distance to the explosion (y-axis) vs. time (x-axis). By applying proximity, audiences can easily depict the entire event a glance and identify different patterns, such as spatial concentration, co-incidence, trends, and divergence. In order to make a powerful design and compelling product, visualization researchers need to integrate these rules and construct what human beings desire to see with little effort.

Gombrich and Constructivist Perception

Gombrich (1977) proposed in Art and Illusion that visual perception is always functioning as a projection of prior experience and imagination, or the so-called constructive. As a constructivist, Gombrich pointed out that artists manipulate the inherited pictorial schemata to directly observe the world, and in turn correct the schemata based on their interaction experience. Gombrich (1977) also pointed out that the ability to recognize objects was the result of perceptual tuning and selection attention. He differentiated looking from seeking, and stated that viewers experience four-step processes of image engagement while looking at images. The four steps include attention (focus), interest (cognitive awareness of the focus), involvement (meaning attached to the awareness), and attitude (feeling resulting from the meaning) (Gombrich 1977). The first step is to be attracted to parts of the image. Then a viewer attaches some meaning to the parts. Thereafter, viewers will normally generate some feeling or attitude towards the image. At this point, looking changes into seeing with a statement of the image. The attitudes, in turn, affect the way viewers perceive the image. The engagement process clearly presents how viewers interact with pictures, and therefore enlightens the visualization design.

Shneiderman (1996) was inspired by Gombrich's schemata and proposed a famous visual information-seeking mantra: Overview first, zoom and filter, then details-on-demand. The mantra has served as a golden rule in visual analytics because it takes human perceptual abilities in current design into consideration. It is very easy for audiences to scan, recognize, and recall images rapidly. Audiences detect changes in size, color, shape, movement, or texture. It is intuitive for audiences to perform tasks like dragging one object to another. Almost all successful visualization design supports the overview, zoom and filter, then details-on-demand. Guo et al. (2014) used dodecagons to visualize GPS data. The system provides an effective overview to show the common patterns. It also allows analysts to filter and examine individual patterns in detail through various interactions.

Arnheim and Gestalt Principles

Arnheim (1969) defined picture perception as the composition of circles, lines, squares, and other forms of graphs into shapes and patterns. The innate laws of the structure are called Gestalt theory. In Art and Visual Perception: A Psychology of the Creative Eye (Arnheim 1974), Arnheim detailed picture-making based on balance, shape, form, growth, space, light, color, movement, dynamic, and expression. Gestalt laws, such as figure/ground, simplicity, completeness, good continuation, and the like were named as fundamental to human perception and visual design.

Visual balance is an innate concept as well as a key principle with which designers convey

messages (Pornstein and Krinsky 1985). Learning visual balance enables designers to create visualizations that "look visually right" (Carpenter and Graham 1971) with respect to color and layout. Arnheim (1974) illustrated the balance concept with a structural net that determined balance. He described that every visual work had nine hotspots and visual elements on the main axes or at the centers that should be in visual balance. Weight and direction led to visual balance. More specifically, the characteristics of visual objects, such as location, size, color, shape, and subject matter, influenced visual balance. In spatiotemporal visualization, it is not an easy task to arrange map elements – legends, scales, borders, areas, place names, and glyphs – into an aesthetically pleasing design. Dent (1999) employed the structural net as a guide for thematic map creation. The research effectively used all spaces and retained a harmonious balance among visual elements.

Arnheim proposed that visual thinking occurred primarily through abstract imagery (Arnheim 1969). Arnheim stressed the importance of reasoning with shapes and identified the nature of abstraction in visual representation. Designers always use visual abstraction to clean up the display and impress observers. When using visual abstraction in information visualization, researchers should keep in mind that the meaning of the raw data sets should be preserved true to their original form. Numerous visual abstraction approaches have emerged in the visualization field. Agrawala and Stolte (2001) presented route maps to depict a path from one location to another. Through specific generalization techniques involving distortion and abstraction, route maps were able to present trajectory in a clear, concise, and convenient form. Lamping et al. (1995) created a novel, hyperbolic geometry approach to visualize large hierarchies. Interaction techniques, such as manipulating focus, using pointer clicks, and interactive dragging, emphasized important actions that viewers tend to focus at the expense of distorting less important information. Humphrey and Adams (2010) employed the General Visualization Abstraction (GVA) algorithm in providing a novel technique for information abstraction, such as selection and grouping. This approach facilitated abstraction by identifying the most relevant information items after assigning an importance value to each item. GVA could be applied to geographic map-based interfaces to support incident management and decision-making. Visual abstraction helps to transfer the meaning of the original data into a slightly different but clearer form. Additionally, visual abstraction also supports the cluttered graphical representation of numerous big data sets by replacing the data with new visual elements corresponding to higher levels of abstraction (Novotny 2004).

Preattentive Processing

Human brains can rapidly and automatically direct attention to information that has the highest salience as well as suppress irrelevant information based on simple computations of an image (Healey and Enns 2012). This is often called preattentive processing and provides the informational basis of attentional selection (Logan 1992). Detection precedes conscious attention. Selection cannot occur until the ensemble coding and feature hierarchy of pre-attentive process is complete.

Many research efforts have tried to address the following central question: which properties of visualizations rapidly attract people? Selective attention usually binds features, such as color, shape, location, and texture, into a perceptual object representation (Wheeler and Treisman 2002). Ware (2012) identified visual properties that are pre-attentively processed in visualization. These are also referred to as pre-attentive attributes that can be perceived in less than 10 ms without conscious effort, and require 200–250 ms for large, multi-element displays. These attributes are grouped into four categories: color (hue and intensity), form (line orientation, line length, line width, line collinearity, size, curvature, spatial grouping, blur, added marks, and numerosity), motion (flicker and direction of motion), and spatial position (2D position, stereoscopic depth, and convex/concave shape based on shading) (Ware 2012). The result, which makes symbols pop out, can be applied to information visualization design.

Five notable theories explain how pre-attentive processing occurs. The feature integration theory proposed a model of how low-level human vision is composed of a set of feature maps that can detect features either in parallel or in serial (Treisman 1991), and a master map of locations that is required to combine featured activities at a common spatial location (Treisman and Gelade 1980). Texton Theory focused on statistical analysis of texture patterns. A group of texture patterns consists of three categories: elongated blobs (e.g., rectangles, ellipses, line segments) with specific properties, such as hue, orientation, and width; terminators (ends of line segments); and crossing line segments (Julesz 1981, 1984). Researchers stated that only a difference in textons or in their density can be detected (Julesz 1981). Instead of supporting the dichotomy of serial and parallel search modes, Duncan and Humphreys (1989) explored two factors that may influence search time in conjunction searches: the number of information items required to identify the target and how easily a target can be distinguished from its distractors. Duncan and Humphreys (1989) assumed that the search ability depends on the type of task and the display conditions. Search time is related to two factors: T-N similarity and N-N similarity (Duncan 1989). T-N similarity refers to the amount of similarity between targets and nontargets that have a positive relationship with search time and a negative relationship with search efficiency. N-N similarity represents the amount of similarity within the nontargets themselves that have a negative relationship with search time and a negative relationship with search efficiency. Guided search theory was proposed by Wolfe (1994). He constructed an activation map for the visual search based on bottom-up and top-down visual information (Wolfe 1994). Users' attention is drawn to the highest hills in the activation map, which generates the largest combination of bottom-up and top-down influences (Healey and Enns 2012). More recently, Boolean Map Theory was presented (Huang and Pashler 2007). Researchers divided the visual search into the two stages of selection and access, and divided the scene into selected elements and excluded elements. This is referred to as a Boolean map. Viewers were able to generate Boolean maps in two ways: by specifying a single value of a feature or applying union and intersection onto two existing maps (Huang and Pashler 2007).

Visual Working Memory

Baddeley (1992) stated that the working memory model consists of a phonological loop that maintains verbal–linguistic information, a visuospatial sketchpad that maintains visual and spatial information, a central executive to control and coordinate the operation of the systems, and an episodic buffer to communicate with long-term memory. Working memory decides which activities to perform, inhibits distracting information, and stores information while accomplishing a complex task (Miyake and Shah 1999). Luck and Vogel (2013) defined visual working memory as the active maintenance of visual information to serve the needs of ongoing tasks. The last 15 years have seen a surge in research on visual working memory that aims to understand its structure, capacity, and the individual variability present in its cognitive functions. There are three essential theoretical issues related to visual working memory: discrete-slot versus shared-resource, visual representation, and visual context.

Visual working memory research has largely focused on identifying the limited capacity of the working memory system and exploring the nature of stored memory representations. The field has recently debated whether the capacity of visual working memory is constrained by a small set of "discrete fixed-precision representations," the discrete-slot model, or by a pool of divisible resources in parallel, the shared-resource model (Luck and Vogel 2013; Huang 2010; Zhang and Luck 2008). Visual working memory allows people to temporarily maintain visual information in their minds for a few seconds after its disappearance (Luck and Vogel 1997). Some researchers proposed that working memory stores a fixed number of high-precision representations when people are faced with a large number of items, and no information is retained about the remaining objects (Luck and Vogel 1997; Pashler 1988; Zhang and Luck 2008). Luck and Vogel

(1997) also stated that it is possible to store both the color and orientation of four items in visual working memory. Some researchers found that both the number of visual objects and visual information load imposed capacity limits on visual working memory up to approximately four or five objects (Alvarez and Cavanagh 2004; Luck and Vogel 1997; Pashler 1988), and six spatial locations represented allocentrically in a spatial configuration (Bor et al. 2001). Thus, the temporary storage of visual information is more related to integrated objects rather than individual features. This statement is also consistent with the selective attention metaphor that visuospatial attention is like the beam of a flashlight. People are unable to split their attention to several locations and are, instead, always paying attention to the most important events while simultaneously filtering out all distractions.

However, other researchers claimed that the visual working memory is able to store imprecise representations of all items, including low-resolution representations of the remaining objects (Bays et al. 2009, 2011; Bays and Husain 2008; Frick 1988; Wilken and Ma 2004). They thought of visual working memory as many low-resolution digital photographs and challenged the concept of working memory by examining the distribution of recall errors across the visual scene. Based on a Bayesian decision model, more visual objects are held in visual working memory and fewer resources are allocated to each object. Thus, in contrast to the discrete slots model, the continuous resource model emphasizes that the storage capacity of the visual working memory is not limited to the number of visual objects. Recent empirical evidence on recurrent neural networks suggests that a discrete item limit is more favorable (Luck and Vogel 2013). Although there is still much ongoing debate regarding the models for resource allocation, there is general agreement that visual working memory has an important object/resolution trade-off: as more items are stored in visual working memory, less fidelity per visual item can be maintained (Brady et al. 2011).

Additionally, what we see depends on where our attention is focused, and our attention is guided by what we store in our memory. Attention and visual working memory are closely connected. The central executive of working memory manages the direction of attention and the supervision of information integration. Moreover, both attention and visual working memory have a limited capacity of visual features that can be detected or maintained. Preattentive processing plays a critical role in which visual properties our eyes are drawn to, and therefore helps people deal with visual and spatial information in working memory.

Cognitive Load

Cognitive load refers to "the total amount of mental activity that the working memory imposes on working memory at an instance in time" (Cooper 1998). Cooper (1998) also stated, "the most important factor that contributes to cognitive load is the number of elements that need to be attended to." Sweller and his colleagues (Chandler and Sweller 1991, 1992; Sweller et al. 1998) identified three sources of cognitive load: intrinsic, extraneous, and germane. The intrinsic cognitive load is determined by the basic characteristics of the information (Sweller 1993). The extraneous cognitive load is imposed by the designer as they organize and display information (Chandler and Sweller 1991, 1992). Designers are always striving to reduce cognitive load and help viewers grasp the underlying information more effectively and efficiently. Finally, the germane cognitive load is the roaming free capacity that uses the extraneous load to build a new, complex schema (Sweller et al. 1998).

Miller (1956) developed our understanding of working memory by using information chunks that could be strung together. He and his followers also believed that working memory had a capacity of between seven and ten chunks at any given time (Merriënboer and Sweller 2005; Miller 1956). In terms of visual working memory, the capacity is limited to approximately four or five visual elements (Alvarez and Cavanagh 2004; Luck and Vogel 1997; Pashler 1988) and six spatial locations where conscious thought transpires (Bor et al. 2001). Generally speaking, visual elements are schemas that can be understood as models that

organize our knowledge. Different people mentally store different numbers of visual objects. Due to the nature of the material, it is almost impossible to change intrinsic cognitive load with design. However, people can control their extraneous cognitive load using design techniques. The level of the extraneous cognitive load may be modified based on how designers present information to users. The germane cognitive load is more so focused on individual self-regulation and concerns schema automation (Paas et al. 2004). Some research posited that the third resource germane cognitive load may have a positive impact on working memory, whereas the intrinsic and extraneous cognitive loads are considered as negative in impact (Sweller et al. 1998). One metric for the evaluation of visualization is to compare the sum of the intrinsic cognitive load and extraneous cognitive load with the working memory capacity. If the additive effect produced by the three resources is less than the working memory capacity, the visualization system involves lower cognitive overload and good usability, which is more likely to be successful. On the contrary, if the sum exceeds the user's working memory capacity, the visualization system has higher cognitive overload and poor usability, which is far less likely to be successful.

Visual working memory has a limited amount of processing power and capacity. Users will get overwhelmed and abandon a visualization task when the amount of information exceeds their visual working memory capacity. The designer must use various design strategies to keep the cognitive load imposed by a user interface to a minimum; therefore, more visual working memory resources are available for activities. Also, cognitive load varies by user. Examples include the involvement required for interaction. For an experienced user, adding interaction may assist them to gain insight from the data. Such interactivity might increase cognitive overload and make the visualization more difficult for the novice user. By reducing extraneous cognitive load with visual analytics techniques, we can minimize the total cognitive load imposed by the visualization interface, which will increase the portion of available working memory to attend to information.

Sensemaking

Sensemaking is the process through which people make trade-offs and construct new knowledge of the world (Weick 1995). These processes include the encoding, retention, and retrieval of information in a temporary workspace or working memory. Sensemaking is constrained by the structure and capacity of working memory; the operation of the knowledge base is constrained by its own nature and architecture (Gilhooly and Logie 2004). Visual analytics is defined as the science of analytical reasoning facilitated by interactive visual interfaces (Thomas and Cook 2005). The field aims to support sensemaking processes and gain insight using an interactive, visual exploration of the data set. However, due to the limited capacity of visual working memory, it is very difficult for people to discover and keep track of all patterns while looking at visualization graphs. Also, inconsistencies between mental models and external representations increase the cognitive overload and thereby further hinder sensemaking outcomes.

There are three phases and loops in the sensemaking process: information foraging, information schematization and problem-solving, and decision-making and action (Ntuen et al. 2010). Information foraging is a cost and benefit assessment of maximizing the rate of gaining valuable information and minimizing the number of consumed resources. Based on the metaphor of an animal foraging for food, information foraging theory helps visualization researchers discover effective ways to represent massive amounts of data and provide effective mechanisms for navigation. Challenges include formalizing contributions, such as identifying trends or outliers of interest, posting explanatory hypotheses, and providing retrieval mechanisms. Information schematization is regarded as an information fusion tool or thinking process that uses new information to explain surprise and update prospective, predictive states of a situation. Decision-making supports situational understanding in which a stimulus is placed into a framework to understand, explain, attribute, extrapolate, and predict a process that leads to situational understanding. Sensemaking deals with seeking, collating, and

interpreting information to support decision-making (Ntuen et al. 2010). Information content is held in active working memory. Sensemaking can be applied to information visualization with the intent to reduce complexity and simplify the volume of data collected in order to create understanding. Visualization can serve to amplify or weaken cognitive ability.

The following section presents two spatial-temporal data visual analytics systems to illustrate how cognitive theories could be applied to the design and development of visualization system.

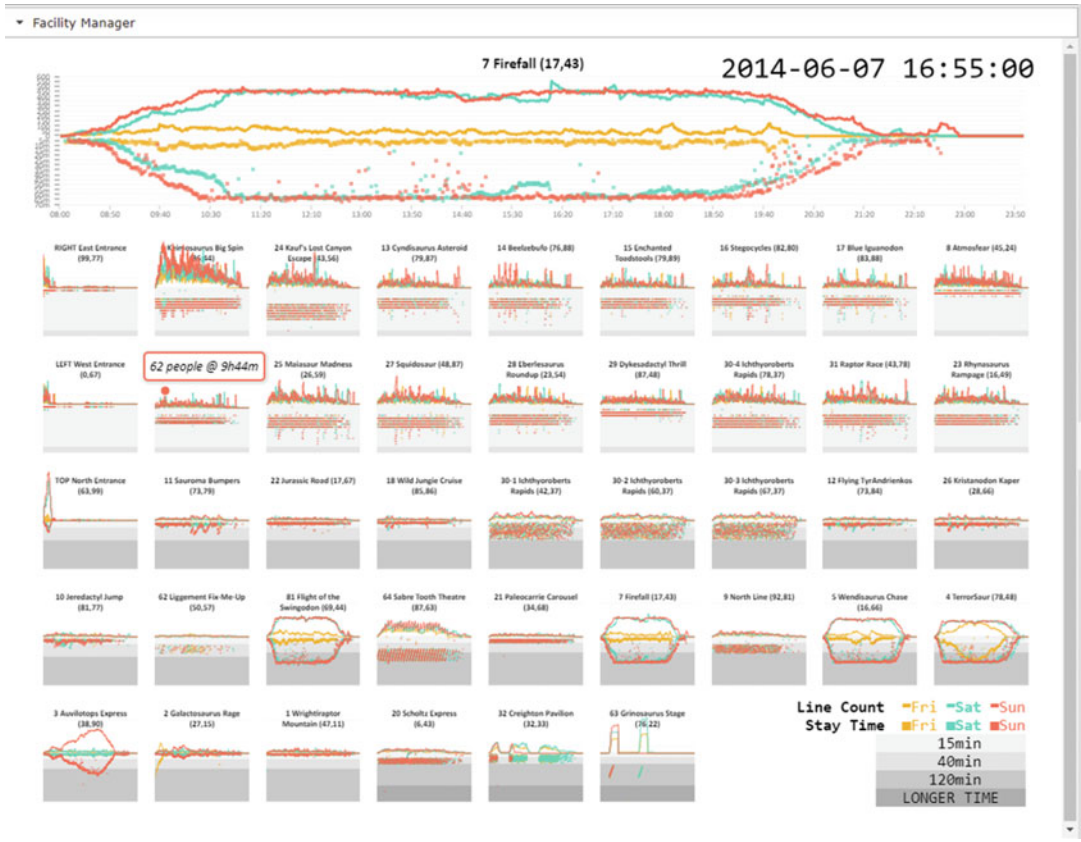
Case Study 1: Vast Challenge 2015 CrowdAnalyzer

CrowdAnalyzer is a system developed from the IEEE Visual Analytics Science and Technology (Vast) challenge 2015 (Wei et al. 2015). With a background that DinoFun World is a typical amusement park, sitting on hundreds of hectares and hosting thousands of visitors every day, a dataset including 3 days' movement tracking information of visitors is provided for researchers to identify the patterns and outliers of attendances and park's activities during those 3 days.

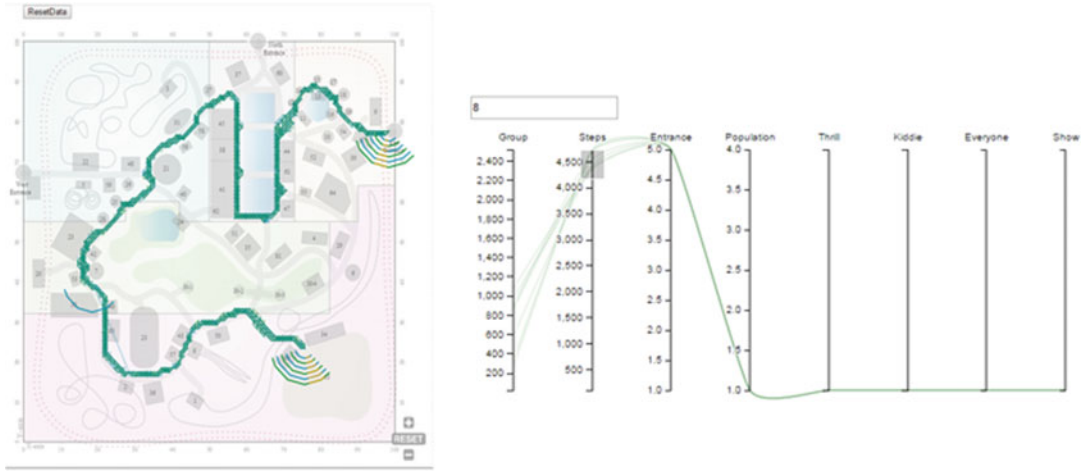
CrowdAnalyzer is designed to visualize visitors' movements, analyze parks' facility status, and identify visitors' group and movement patterns. The system has four parts: facility manager, group hierarchical inspector, enter-leave time group viewer, and map (Fig. 1). Due to the huge amount of data, it is impossible to present the data at once. CrowdAnalyzer allows the viewer to get an overview first and then decide which area of the map they did like to further investigate through zooming in and filtering the details of the data.

The tab "Facility Manager" presents the parks' entertainment facilities' status: the number of people waiting and the estimated waiting time. Multiple line charts are used to present the data. The positive y-axis represents the number of people, the negative y-axis is the waiting time, and the x-axis is the timeline. The colored points on the coordinate show the number of people waiting to take the ride at the corresponding time points. According to Arnheim (1969), people will interpret the composition of different forms of graphs into shapes and patterns. The user will automatically categorize the same color dots into a group. The good continuation between the same colored dots will make them into a line from Gestalt principles of perception (Arnheim 1974). The line depicts the waiting people and the waiting time's change through time, and the distinct colors differentiate the data on different days. In Fig. 1, people will know that the waiting people and time on Friday is much lesser than the weekend.

To reduce users' visual working memory, in CrowdAnalyzer, every visualization has a legend on the corner. Windows are arranged side by side to convenient users' exploration and comparison. Hundreds of thousands of tourists visit the park in 3 days. To reduce users' workload from both perception and memory aspects, it is important to categorize visitors into typical groups. Researchers applied statistical analysis (K-means and EM algorithms) on data criteria (such as visiting date, entering location, and population) to cluster individual tourists into hundreds of small groups. Then visualize these groups using parallel coordinates. The parallel coordinates have eight vertical axes (group ID, walking steps, the number of the entrance, group population, the number of thrill rides, the number of kiddie rides, the number of everyone rides, and the number of shows). The line connecting axes represents a typical visitor group. Users can filter on the parallel coordinates to figure out patterns and outliers. For example, in Fig. 2, the groups that haven't taken any rides but entered the park many times are picked out. The groups' moving trajectories and the key time points are presented on the map. There are two groups of concentric arcs on the map. Each arc represents one group. The arcs with the same radius represent the same group, so we know there are six groups of visitors. As the parallel coordinates show there are only one people in each group, there are six people in total. The start point of the arc represents the visitor's entering time, and the end of the arc represents the visitor's leaving time. We can tell that six people entered and left the park at the same time. The yellow color on the arc represents the duration that



Cognitive Processing of Information Visualization, Fig. 1 Facility manager in CrowdAnalyzer



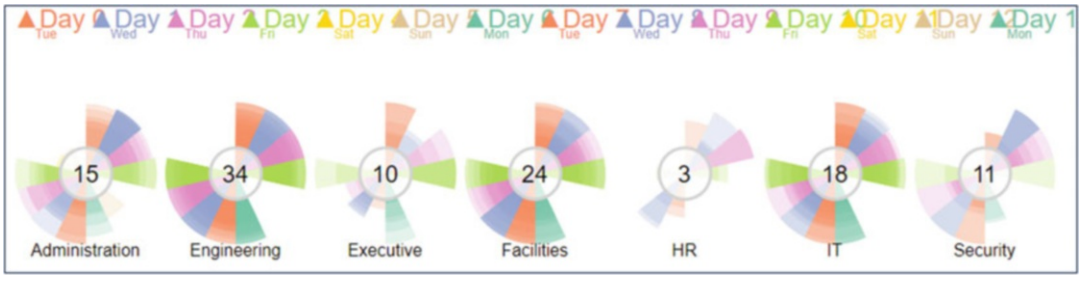
Cognitive Processing of Information Visualization, Fig. 2 Enter-leave time group view and parallel coordinates in CrowdAnalyzer

the visitor stayed at the place on the map. In conclusion, from the trajectories and arcs on the map, the six people arrived and left the park at the same time, shared exactly the same path, took a rest at the entrance before entering the park, then took a rest again at the other entrance of the park. Then, we can reasonably consider these people are not visitors but the park staffs who are responsible for float performances. They performed on a fixed route, repeated the performance five times each day, and took a rest after the performance was done. Through filtering out abnormal data on parallel coordinates and presenting detail information on the map, users are able to observe and understand the characters of different types of visitors.

Case Study 2: Vast Challenge 2016 Metacurve

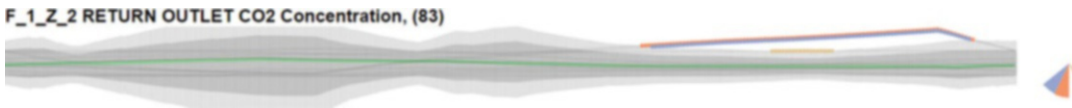
The second system MetaCurve aims to help analysts interpret and analyze periodical time series data using IEEE VAST 2016 mini Challenge 2 dataset. The dataset registered an office building's temperature and HAVC (heating, ventilation, and air conditioning) system status in 2 weeks, and the employees' movements in the building. The first section of MetaCurve is the movement patterns and outliers of employees. Summarized pie charts (Fig. 3) are designed to attract users' attention and guide users to click the pie charts to explore more. In Fig. 3, fourteen arcs make up a pie chart. Color is used to differentiate different arcs, and the black stroke between arcs strengthens the boundary of arcs. The radius of each arc represents the number of outliers of employees' movements. Although in the weekend, employees took breaks and the arcs are not shown, people still have the visual ability to make up the absent part, recognize the pie chart, and further understand the information that pie chart is designed to express. The seven pie charts showing movement anomalies of seven types of employees present that the movements of employees from the administration, engineering, facilities, and IT departments are more flexible than the employees of the executive, HR, and security department.

By clicking on each pie chart, a detailed visualization combining coordinate, color, shade, and shapes are provided (Fig. 4). Human is sensitive to the difference in color, shape, and shade. Different visual factors are adopted to take advantage of human visual perception. The x-axis of the coordinate in Fig. 4 is the timeline. The y-axis is corresponding to the building floors and zones. From the bottom of the y-axis (first-floor zone 1) to the top (third floor zone 7), each proximity zone is presented. As employee's movement data is periodical data, their proximity records are stacked together in the chart. If an employee appeared at a zone less than four times in 2 weeks, a light shade would be marked at the time. If the appearance time is only once, a dot will be marked on the shade. The orange line marked on the zone shows the location of the employee' office. Figure 4 clearly depicts the movement differences between a security people and an administer.



Cognitive Processing of Information Visualization, Fig. 3 Pie charts in MetaCurve

Cognitive Processing of Information Visualization, Fig. 4 The timeline chart showing the movement differences between a security people and an administer



Cognitive Processing of Information Visualization, Fig. 5 Statistical measurements of CO2 concentration in MetaCurve

The building temperature and HVAC data are also periodical data, which is overlaid onto the timeline in MetaCurve. For continuous data, such as CO2 concentration in Fig. 5, after using statistical measurements to compute the median value, variation, and interquartile, the range between the first quartile and the third quartile is plotted using color and considered as a normal data range. The data points located out of the range are considered as major outliers and marked with dots. The color of dots is corresponding to the date.

By using colorful pie charts, MetaCurve firstly attracts users' attention and then provides detailed spatial-temporal information through combining coordinate, color, curve, and shapes.

Conclusion

The information visualization field is a multidisciplinary field and this field still lacks sufficient theoretical foundations that inform design and evaluation. This paper provided an overview of the literature related to the cognition theories of information visualization. It introduced the underlying cognitive knowledge and the basic perception theories central to the development of the ideas in visualization. The two case studies of information visualization show how the basic cognition theories inform and impact the design and development of information visualization. Investigating the cognitive processing of information visualization can provide a useful way for researchers to describe, validate, and understand

the design work. The value of theories in cognition and perception can further defend and secure the information visualization discipline.

Cognitive Psychology Applied to User Experience in Video Games

Celia Hodent
Epic Games, Cary, NC, USA

Synonyms

HCI; Human Factors; Human-Computer Interaction; UX; UX Design

Definition

The user experience (UX) entails a person's perceptions and interactions with a product or software (such as a video game) and the satisfaction and emotions elicited via this interaction. UX overall refers to an overarching discipline focused on evaluation and improvement of users' experience of a given product or software in development.

Cognitive psychology is a discipline dedicated to understanding the human mind via mental processes such as problem solving, language, perception, attention, and memory.

Introduction

The designer Donald Norman popularized the notion of user experience (UX) in the 1990s (Norman et al. 1995). Originating in the fields of human factors and human-computer interaction, UX as a discipline incorporates knowledge and methodologies from behavioral sciences – including cognitive psychology – to evaluate the ease of use and emotions elicited from a product or system. Video game studios have increasingly turned to this relatively new discipline to ensure that the games they develop offer a compelling experience to the targeted players. The inclusion of UX considerations in the design process saves rather than costs a studio money as it allows for more successful game development, contrary to some misconceptions (see Hodent 2015). According to game designer Tracy Fullerton, to design a game is to create an "elusive combination of challenge, competition, and interaction that players just call 'fun'" (Fullerton 2014, p. XIX). However, no objective definition of fun has emerged, nor any detailed parameters to attain it. UX offers a framework to ensure that the experience intended is the one ultimately felt by the target audience. UX representatives use guidelines (heuristics) and methodologies (user research) to anticipate and evaluate how end users interact with a specific game, software, or service and the emotions elicited via this interaction.

Considering the Player's Mind

The user experience of video games happens in the player's mind (see Schell 2008). An important perspective when considering video games' UX is that the game designers and end players may invoke different mental models. Norman described mental models in his seminal book *The Design of Everyday Things* (Norman 1988). According to Norman, a system (such as a video game) is designed and implemented based on the designer's mental model of what the system should entail and how it should function. Players then develop their own mental model of how *they* think the game works through their interactions with it, given their prior knowledge and expectations. The main objective of UX is to ensure that users experience the game (the system image) the way the game developers intended, through players' perception of the game and their interaction with it. The developers have to adjust the vision of the game in development to comply with the limitations of the system (e.g., platform, performance) and the limitations of game production resources (e.g., timeline, workforce). Similarly, the developers must comply with the capabilities and limitations of the human mind to offer a compelling experience to the players. Playing a video game is a learning experience, from discovering the game to mastering its subtleties. Information that the brain processes originates from perceived input that then impacts the memory of a subject. The quality of the processing – and ultimately the quality of the retention – depends highly on the attentional resources applied, which are also dependent on the emotions and motivation felt by the players. Thus, to improve the experience of the players, video game developers must take into account the perception, memory, and attention limitations of the brain, as well as the emotions and motivation felt by the players.

Perception

Perception involves all the mental processes that allow us to sense our environment and construct our own mental representations of it. Thus, these

processes are bottom-up proceeding from sensation to cognition (access to semantics) and also top-down whereby cognition (i.e., previous knowledge, expectation) impacts one's sensations. For example, the save icon (usually symbolized by a floppy disk) is likely meaningless to young children who do not have a mental representation for this object, until they learn what it symbolizes when using a computer. This example illustrates that perception is subjective. It varies depending on the context in which the input is presented and on one's previous knowledge or expectations. Therefore, game players or technology users may understand a specific element differently than what the designer had intended. To ensure that the game menus and signs and feedback will be understood as designed, it is important to assess them with the end users during usability tests whereby, for example, a sample of target users are presented with icons and they have to explain what the icons look like and denote. Ideally, the form (shape) of an icon should correctly inform the players about its function (what it does or how to interact with it).

The signs in a video game refer to all the perceptible cues that either urge the player to execute a specific action or inform the player of a system status. For example, a yellow exclamation mark above a nonplayer character (NPC) encourages the player to interact with that NPC. Other signs, such as a green bar or red hearts, may inform the player of a system status, such as the avatar's health. Game feedback is the reaction of the system to the player's action. For example, an avatar may animate when the player uses the thumbstick or WASD keys. Another example is the ammunition count depleting when the player is shooting. Overall, all possible interactions should have signs and feedback associated with them. These signs and feedback, and the user interface overall, should be perceptible and provide enough clarity to help the player understand the game mechanics. The Gestalt principles provide useful guidelines that should help designers organize the game interface in a way that will be correctly understood by the players (see Johnson 2010, for examples in software design). Gestalt principles account for how the human mind perceives and organizes the environment (Wertheimer 1923). For example, the Gestalt law of proximity describes how elements that are close to one another are interpreted as belonging to the same group. When considering the heads-up display (HUD) of a game, displaying the icons and symbols representing features that are related next to each other enacts this law. Thus, it is what the end players subjectively perceive and understand about the game interface that matters, not the reality of what the developers and designers have implemented.

Memory

Memory allows us to encode, store, and retrieve information and has been seen as comprised of sensory memory, working memory, and long-term memory (Atkinson and Shiffrin 1971; Baddeley 1986). Sensory memory is part of perception and retains sensory information for a very short period of time (such as a fraction of a second) without it being consciously processed. For example, the persistence of vision (e.g., fleeting images) reflects sensory memory, which allows us to perceive a 24-image-per-second display as an uninterrupted animation. Working memory is a short-term component that allows for temporary storage (e.g., a few minutes) and manipulation of a very limited amount of new or already stored information. This system maintains active mental representation necessary to perform a task. For example, performing a mental calculation entails keeping numbers active in the working memory while manipulating them. Working memory requires substantial attentional resources (see the description of "attention" below) and therefore is very limited in duration and capacity. In fact, learning can be hampered and result in cognitive load when work-memory limits are exceeded (Sweller 1994). Long-term memory is a multiple-system component that allows us to store knowledge of events and skills (know-how). Long-term memory has no known limits and is seen as potentially storing information indefinitely although forgetting is possible.

In 1885, the psychologist Hermann Ebbinghaus illustrated with the forgetting curve how memory retention declines exponentially

with time (Ebbinghaus 1885). Retention of information, especially if not engaging emotionally or meaningful, can be very fragile. Some variables have an impact on the strength and quality of the encoding and storage of information, such as the level of processing (the deeper the process the better the retention) and the amount of repetition over time. Not only the brain is prone to memory lapses, but it can also distort memories. Because of these limitations, developers cannot rely too heavily on players' memories. Even if some information has been encoded via tutorials during the onboarding part of the game, it is likely going to fade with time unless used regularly. This is why it is generally a good practice to reduce to a minimum the information that the players have to remember in order to enjoy the game (i.e., mechanics, controls, objectives) and to give frequent reminders, especially since a long time can elapse between two gaming sessions. It is also important to prioritize the information players have to learn and to distribute learning over time. Lastly, the strength of retention can be increased if the players can learn by doing (see Lesgold 2001) in a meaningful context – instead of first reading tutorial texts and then doing. Therefore, it is a better practice to place the players in a situation when they have to execute a new action to accomplish an immediate goal. For example, placing a chest beyond a hole is a meaningful and active way to teach players about jumping and looting mechanics.

Attention

Our senses are continuously assailed by multiple inputs from our environment. Attention entails allocating more cognitive resources to process selected inputs while the others will be ignored (selective attention). The brain's attentional resources being very limited, we do not methodically process all the available information from the environment. Instead, attention works like a spotlight, focusing resources to process and retain particular elements and neglecting the other inputs. For example, when in a loud and crowded cocktail party, one can pay attention to a specific conversation but cannot process all the other conversations at earreach; these are suppressed from conscious attention. Only an attention-grabbing event – such as a sudden loud sound or light flash – can then draw attention away from the current information attended. When attention is divided, for example, when driving while having a conversion over the phone, it requires more cognitive load to process the different information, therefore leading to more fatigue and mistakes. In fact, the brain cannot usually multitask efficiently; either one task or both are performed less efficiently, unless at least one of the tasks is very simple or automatic (such as chewing gum while reading). Similarly, the more demanding a specific task is in terms of cognitive load (e.g., complex mental calculation), the less a subject can allocate mental effort to accomplish another task, even though simple (such as pressing a button when a red light goes off; cf. Kahneman 1973). Subsequently, the more attention is allocated to a task or information, the better it will be retained, therefore learned, as seen in the "Memory" section above. Thus, it is critical to draw the players' attention to the elements that they need to learn. Given that all of our mental processes are using the same limited attentional resources, the developers must mind the cognitive load the game demands from the player, especially during the onboarding of a video game, when the players have a lot of new information to process.

When elements are unattended, they are likely not perceived at all, in a phenomenon called inattentional blindness (Mack and Rock 1998). This phenomenon was best illustrated in the well-known "gorilla" experiment (Simons and Chabris 1999) whereby subjects had to watch a video in which two teams of people were moving around and passing basketballs. One team was wearing black shirts and the other team white shirts. The subjects were asked to count basketball passes made by players of the white team only. In the middle of the video, a person in a black gorilla suit walked into the scene, pauses, and then walked off the scene. The results showed that most subjects, directing their attention into counting the basketball passes from the white team, missed the gorilla although quite prominent in the scene. This study explains why players, when focused on a task, can stay blind to any

other information conveyed at the same time. For instance, if tutorial text information about the health mechanic is displayed while the players are experiencing their first combat, they will likely not process or even perceive that information as all their attention is focused on surviving their first enemy encounter. Therefore, it is preferable to avoid displaying important information when the players are directing their attention to another task.

Emotion and Motivation

According to Norman (2005), "the emotional side of design may be more critical to a product's success than its practical elements" (p. 5). The emotional aspect in video games is frequently addressed through aesthetics, music, or narrative. However, an important aspect of emotional game design has to be considered as well: the "game feel." Game designer Steve Swink (2009) describes game feel as including "feelings of mastery and clumsiness, and the tactile sensation of interacting with virtual objects" (p. 10). Accounting for the game feel involves carefully designing the camera, controls, and characters. For example, if the camera of the game has a very narrow field of view (FOV) it may give players a feeling of claustrophobia, which would be inappropriate for a peaceful exploration game. It could however be appropriate for a horror survival game, depending on the game design intentions.

Players' motivation is another important variable to consider when developing a game. According to Przybylski et al. (2010) "both the appeal and well-being effects of video games are based in their potential to satisfy basic psychological needs" (p. 154). Therefore, a game that satisfies basic psychological needs for competence, autonomy, and relatedness (c.f. Deci and Ryan 1985) will more likely be engaging. Competence entails the players' sense of mastery and feeling of progression towards clear goals (i.e., Nintendo's *Legend of Zelda* series require increasing mastery to progress in the game). Autonomy encompasses offering meaningful choices to the players and opportunities for self-expression (i.e., Mojang's *Minecraft* allows the player to experiment with the game environment in a creative way). Relatedness involves primarily the need to feel connected to others. Relatedness in games is often addressed through multiplayer features allowing players to interact with each other in real time or asynchronously, via cooperative or competitive goals. Sustained motivation and emotional connection both have an impact on the enjoyment of a game. These components also have an impact on the learning experience and the quality of information retention.

Usability and Gameflow, the Two Components of User Experience in Video Games

To ensure a good video game user experience, it is important to consider its usability and gameflow. Making software – such as a video game – usable means "paying attention to human limits in memory, perception, and attention; it also means anticipating likely errors that can be made and being ready for them, and working with the expectations and abilities of those who will use the software" (Isbister and Schaffer 2008, p. 4). Usability is about removing or at least alleviating all the frustrations and confusion the player could experience while playing the game, if they are not intended by design. Broad guidelines – heuristics – can be used to attain usability. Many usability heuristics have been developed, both in web (e.g., Nielsen 1994) and game design (e.g., Desurvire et al. 2004; Laitinen 2008). These heuristics take into account the human brain capabilities and limitations in perception, attention, and memory described earlier. The gameflow component refers to how enjoyable and engaging the video game is. It takes its roots from the notion of flow, described by psychologist Mihaly Csikszentmihalyi as the optimal experience whereby "a person's body or mind is stretched to its limits in a voluntary effort to accomplish something difficult and worthwhile" (Csikszentmihalyi 1990, p. 3). The gameflow component offers a set of criteria, or heuristics, to improve the emotion response and motivation felt by the players, in an

adaptation of the concept of flow into games (Chen 2007; Sweetser and Wyeth 2005). By considering both usability and gameflow heuristics, a UX framework can be developed to provide a useful checklist for game developers (see Hodent 2014a, for an example of a UX framework applied to game design).

Conclusion

To warrant an engaging and enjoyable user experience, game developers need to consider human capabilities and limitations by adopting a UX framework (Hodent 2014b). Such framework is taking into account the limitations of the human brain in perception, attention, and memory. It also considers the emotional response and motivation felt by the players. It can be used during the development of a video game as a checklist to ensure that the usability and gameflow guidelines are respected, therefore increasing the chances of offering a compelling user experience to the targeted audience. A UX framework provides game developers with useful guidance to improve the quality of their game and ensure that their intended design is the one experienced by the target audience.

Definitions

Computer Aided Design (CAD) and Computer Aided Engineering (CAE) are now benefiting from advantages of virtual reality systems in terms of visual collaboration between engineers, designers, and customers, reducing prototyping costs and minimizing required design and development time.

Introduction

Virtual prototyping is a method in the process of product development. It uses outputs of Computer Aided Design (CAD) and Computer Aided Engineering (CAE) software to validate the design before making a physical prototype. Traditionally, it is done by using one or combination of more than one 3D computer software to generate geometrical shapes and combining them in order to test mechanical motions, functions, and fit. These geometrical shapes represent parts of the project and they could be manipulated by CAE software to simulate the behavior of the part in the real world.

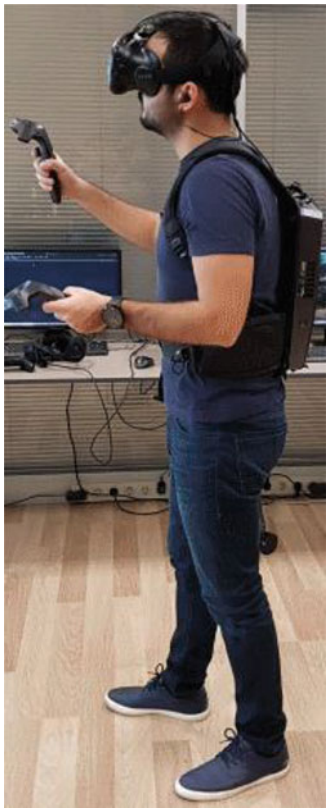
With the introduction of affordable consumer and enterprise head-mounted displays (HMD), engineering groups started to study about implementation of virtual reality technology in order to provide new pathways for engineers, designers, and their customers to experience new products and development processes, without the need of making physical prototypes and mock-ups. Virtual reality can provide any HMD equipped engineer, designer, or customer to have realistic digital prototypes accessible in any place with instant manipulation and assembly/disassembly capabilities.

Background

The product design and development process was used to rely primarily on engineers' experience and judgement in producing an initial concept design. Engineers were using CAD software for designing parts in basic geometrical shapes in a 3D environment; then designed parts were converted to 2D engineering drawings in order to produce them in Computer Numerical Control (CNC) machines without any way to evaluate its performance in advance. The initial prototype was highly unlikely to meet expectations. Engineers usually had to redesign the part multiple times and weaknesses were revealed only in physical testing.

Nowadays, customers are requesting more customized products in high-quality standards

with affordable costs and shorter lead time. This understanding causes a significant increase in product variety and competition in the market. Manufacturers are under pressure to reduce the production time, cost and optimize products to higher standards of performance and reliability. Manufacturers are changing their design and manufacturing processes in order to keep up with the customer demands. Latest progresses revealed that having feedbacks from customers in every step of design and manufacturing process is highly important, even if the product is in the idea phase (Tseng et al. 1998). This approach enabled the utilization of concurrent engineering in design and manufacturing processes. Today, with the help of immersive technologies such as virtual reality and augmented reality, engineers, designers, and customers are constantly able to evaluate the product in functionality, reliability, and aesthetic dimensions and give their feedback in order to change the product design in the design phase without the need of creating physical prototypes (Vosniakos 1998).



Collaborative Engineering and Virtual Prototyping Within Virtual Reality, Fig. 1 HTC Vive usage with a backpack PC

Utilizing Virtual Reality

Virtual reality gives an opportunity to experience any product in any phase with the support of photorealistic visuals, dynamic lights and shadows, simulated physics and dynamics without creating a physical prototype. Also, it is possible to assemble, disassemble, and test mechanical motions of 3D CAD models in virtual environment with the collaboration of multiple participants such as designers, engineers, and customers. This can be done using only an HMD and a computer in any physical space. In order to use it, users need to put the HMD onto their heads and use controllers for manipulating objects as shown in Fig. 1. They also have an opportunity to use real life navigation such as walking and crouching, which give an opportunity to users for walking around the object, looking closer to it from different angles in real time, as if looking to a physical prototype. With the help of built-in or external tracking systems, virtual reality systems can register an arm, hand, and finger movements, which gives the user an opportunity for manipulating, assembling, or disassembling 3D objects in the virtual world with collaboration.

Using an HMD-based virtual reality device is also cost-effective over 3D projection systems such as spherical or CAVE-type virtual environments. These environments require special 3D projectors, projection screens, and a significant physical space. Devices such as 3D projectors are very expensive for utilizing, operating, and maintaining. Also, projection environments need a dedicated space, and it is not possible to use it as a mobile system. Today, HMDs are in the consumer market with affordable prices and they only require a gaming PC and no dedicated space at all. Manufacturers can use HMD-based virtual reality systems for off-site demonstrations or collaborated projects.

In order to use a virtual reality system for collaboration and virtual prototyping, required virtual world must be created with the help of special software. Most of the features for a development of such a virtual prototyping platform are available in game engines supported by the game development industry, which has a value of 25.1 billion USD according to 2010 ESA reports. However, since game engines are developed for making games, some of the specific features are not available and some features do not meet requirements of virtual prototyping standards. As a solution to that problem, some virtual reality and simulation companies started to develop virtual prototyping platforms. One of them is Augmea Immersive Platform (AIP), which is developed by Augmea Simulation Technologies A.S. and it uses the power of state-of-the-art game engine, CryEngine (Altundag et al. 2017). Software products like AIP gives an opportunity to manufacturers for creating virtual worlds in order to use the best features of virtual prototyping technologies in industry standards with cost- and time-effective approach.

Conclusion

Utilization of the virtual reality technology for virtual prototyping gives an important opportunity to manufacturers for experiencing the design, assembling, and disassembling them in order to evaluate the performance of parts or the whole product without the need of creating physical prototypes. Designers and engineers can work together for evaluation and collaborative design, even in different physical locations. They are able to use full body movement, controllers, and sensors in the virtual environment with the photorealistic visuals, dynamic lights, shadows, and simulated physics. HMD-based virtual reality devices are cost-effective over 3D projection systems, and they do not need dedicated installation spaces. With the introduction of affordable HMD devices and special virtual prototyping software, virtual reality can provide any HMD equipped engineer, designer, or customer to have realistic digital prototypes and collaboration space.

Definition

Collaborative environments for augmented and virtual reality applications are virtual environments which can be experienced by more than one user to cooperate in a collaborative task.

Collaborative environments can be designed to be compatible with augmented reality (AR) interfaces, virtual reality (VR) interfaces or both.

Introduction

Human communication and collaboration through digital systems have been the focus of research for more than 30 years. This research field is known as Computer Supported Cooperative Work (CSCW). Though CSCW can greatly benefit from AR and VR, only recently AR and VR have reached technological progress that enables researchers to focus on exploiting these technologies to support collaboration through collaborative environments (CEs). Tech companies such as Microsoft, Vive and Apple are continuously developing new hardware and software to support AR and VR, and among the various application fields, the creation of collaborative systems is widely accepted as one of the most valuable ones.

The design of CEs, the technologies adopted to create and experience CEs, and the most common applications' fields are discussed in this chapter.

Technologies

Computer-generated CEs are based on 3D real-time engines, which enable designers to represent the digital contents to be displayed to the users. Unity 3D (Fig. 1) and Unreal Engine are the most known software adopted for designing and implementing virtual environments, whereas many other 3D engines exist, either licensed (e.g., CryEngine) or open source (e.g., Blender). A 3D engine allows designers to create a virtual environment, furnish it with virtual objects, script the objects' behavior, and design and develop the user interaction layer.

Once the virtual environment is available, the second relevant technology necessary to deploy a CE is the physical interface adopted to experience it. Milgram's Reality-Virtuality Continuum (Milgram and Kishino 1994), depicted in Fig. 2, is widely adopted to explain the design space of mixed reality interfaces. Among the physical environment and the virtual one there is a continuum of systems, which merge the physical and virtual world, known as Mixed Reality: depending on the balance of physical and virtual elements, it is possible to further distinguish between augmented reality (AR) and augmented virtuality (AV). An AR system adds virtual elements to a direct or indirect representation of the real world, whereas an AV system adds real elements to a virtual environment.

AR environments are experienced through either video see-through or optical see-through devices (Fig. 3). Video see-through devices record the physical world through a camera and display it combined with the digital contents. These devices can be

further classified as desktop (e.g., a computer and a webcam) or mobile (e.g., smartphones and tablets).

VR environments are experienced through either traditional displays, which can be classified as mobile or desktop, or immersive virtual reality headsets, which consist of closed helmets with two displays in front of the user's eyes, thus detaching people from the real environment (Fig. 4).

Overall, a CE can be designed to be compatible with both VR and AR devices: whereas VR users will experience a complete virtual world, AR users will see only a subset of virtual elements, which do not inhibit the perception of the reality. This can be obtained by scripting accordingly the behavior of the elements of the virtual environment, depending on what the AR users should see.

	Synchronous (same time)	Asynchronous (different time)
Colocated (same place)	Face to face interactions	Continuous task
Remote (different place)	Remote interactions	Communication & Coordination

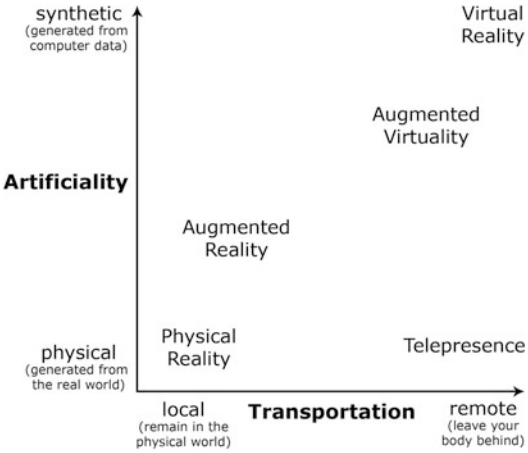
Collaborative Environments for Augmented and Virtual Reality Applications, Fig. 5 CSCW Time-space matrix

Design

The first step in the design of a CE is to define the level of collaboration required or expected for a given task. Since CEs for AR and VR are a specific type of CSCW, the time-space matrix proposed by Johansen (1988) depicted in Fig. 5 provides a clear representation to understand possible typologies and requirements for collaborative activities. The collaboration can be synchronous or asynchronous, whereas the users may interact in the same physical space or they may be located in different places.

Benford et al. (1998) proposed a more complex taxonomy, which combines together the time-space matrix and the reality-virtuality continuum based on three dimensions: artificiality, transportation and spatiality (Fig. 6). Artificiality represents the ratio of virtual content and real content in the collaborative environment, e.g., a completely synthetic world for a VR system or a physical world enriched with digital assets for an AR system.

Transportation defines how much the user is detached from its environment and moved to a remote environment. This feature should not be confused with Artificiality, since the collaboration can either take place in the user environment or in a remote environment through telepresence, and in both cases, AR and VR would not be involved since the Artificiality would be at the bottom level. Spatiality defines how much the collaboration involves a common spatial frame. For example, a collaboration through a chat box would have no spatial reference, the usage of a 2D dashboard would consist of a limited shared spatial frame, whereas a shared virtual environment involves a 3D Cartesian shared spatial frame.



Collaborative Environments for Augmented and Virtual Reality Applications, Fig. 6 Artificiality and transportation dimensions of Benford's taxonomy

The time-space matrix and Benford's taxonomy are valuable tools to understand the different types of collaborative environments. Moreover, it is possible to talk about symmetric collaboration if all the users experience the shared environment by the same level of transportation, spatiality, and artificiality. Examples of the symmetric collaborative environment are two users located in the same space and collaborating through AR, or two users experiencing the same virtual environment through immersive VR. Asymmetric collaboration instead takes place when at least one of the three dimensions of Benford's taxonomy differs from one user to another. An example could be a user who interacts in his/her physical space through an AR device and a remote user

collaborating into a digital twin of the real environment through immersive VR.

Application Fields

CEs are broadly used in several domains and the most important ones are the following: collaborative design, education and training, industry, medical scenarios, tourism, and cultural heritage. Motivation for adopting CEs and examples are introduced and discussed for each one of these research fields in the following sections.

- In the Architecture, Engineering, Construction, and Operation (AECO) area, collaboration and interaction are of primary importance, and architects, engineers, and subcontractors must collaborate closely during each design phase. The project team should make high-quality decisions and innovations by combining the experience and expertise of various professionals. As the complexity of the projects increases, the corresponding amount of data and information increases too, thus potentially generating an uncontrolled working environment. Furthermore, in AECO scenarios, operations and resources are frequently distributed among several actors that may be positioned in different physical locations. Thanks to technological advancements, CEs can effectively exploit VR and AR technologies, thus providing physical embodiment, immersive experiences, and high levels of interaction. Users can obtain an immediate feedback on the design process regardless of the physical location of the involved actors. Blueprints, construction plans, and design sketches can be displayed in the collaborative environments allowing users to provide inputs and changes that are applied on the fly to the virtual assets. Figure 7 shows an example of a collaborative meeting done using AR interfaces.

Representative works are (Lin et al. 2015; Ibayashi et al. 2015). Lin Liu Tsai et al. (2015) proposed a co-located, synchronous AR system to improve discussions related to construction processes. Public data can be visualized using stationary displays whereas private information is directly conveyed to the mobile devices of the involved users. The stationary display consists of a tabletop interface with a dedicated personal computer whereas the mobile devices are represented by Android mobile tablets. Data displayed on the stationary display can be modified via tangible interaction paradigms, that is, the

Collaborative Environments for Augmented and Virtual Reality Applications, Fig. 7 An example of a CEs for AECO seen through AR. Photo by Patrick Schneider on Unsplash

users can manipulate the virtual information by using paper markers tracked with an external camera. The authors compared their system with traditional paper-based approaches, and the main outcomes show a great reduction in the task completion time. Regarding architecture, Ibayashi et al. (2015) presented a synchronous VR system to improve the design phase of architecture sketches. Several users can interact with the same virtual sketches by using two different modalities: a first-person view (by an immersive VR device) to see the fine local details and a top-down view (by a tabletop interface) to have an overview of the entire project. One interesting capability of the proposed system is the so-called "God-like" interaction technique. When the users are touching a specific object of interest on the tabletop interface, the VR users can clearly detect the same object of interest by visualizing a 3D representation of a human hand that pinpoints the objects. Although the system has been described as a co-located scenario, it can be easily extended to a remote one.

- Education and training can greatly benefit from collaborative environments. By presenting educational content in the 3D virtual space, learners can easily and effectively understand structured and complex subjects, especially the ones coming from the mathematical or engineering domains. Furthermore, by exploiting participatory design and gamification techniques, users can improve their knowledge by being directly involved in the learning process. In collaborative environments, two or more users collaborate and learn together to achieve a common goal (Laal 2013). Due to this strong link among learners, users are responsible for their own learning process and that of others (Doymus 2007; Gokhale 1995) (a representative example is shown in Fig. 8).

Some representative works can be found in (Punjabi et al. 2013; Pareto 2012). Punjabi et al. (2013) presented CrowdSMILE, a remote, asynchronous system to effectively handle learning data coming from different sources and tools.

Collaborative Environments for Augmented and Virtual Reality Applications, Fig. 8 Usage of VR headsets for education. Photo by stem.T4L on Unsplash

Contents can be explored using desktop and handheld interfaces, which are used by three different components: (i) *POI Explorer Application*, (ii) *Social Publisher Client Application*, and (iii) *CrowdSMILE Server*. The first component runs on Android mobile devices integrating AR technologies to display learning contents related to the physical environment. The second component allows the users to publish new learning material that will be then explored by the POI Explorer Application. The users can add new location-based learning material by means of handheld and desktop interfaces. The third component provides the main functionalities of the system allowing the exchange of data between the remaining components. The system has been evaluated through a series of user studies showing high levels of usability. Pareto (2012) proposed a co-located, synchronous environment to improve the learnability of mathematical concepts for children with intellectual disabilities. Users can play a series of 2D games to foster reasoning skills and strategic thinking. The games can be experienced using desktop interfaces, interactive whiteboards, and interactive spatial AR systems. The system has been assessed through a series of user studies and the main results show that the gameplay can improve the students' "number-sense" whereas the graphical representation of numbers can greatly assist the students to accomplish mathematical problems they had never been able to solve.

- Industrial scenarios have been also deeply considered and evaluated. CEs have been mainly used for Assembly-Repair-Maintenance (ARM) tasks by leveraging the traditional local-unskilled remote-skilled interaction paradigm. The remote expert tries to help the local unskilled user through a series of procedures and both users interact in the collaborative environment by using a combination of AR and VR devices. In such environments, conveying effective instructions becomes of primary importance, and researchers have devoted great effort to understand which virtual metaphors should be used to improve ARM tasks. Early researches have explored the use of abstract metaphors, such as virtual arrows or generic shapes controlled by the remote user. More recently, the visualization of human body parts by the remote expert has been researched, showing that displaying user's hand gestures in the local user real environment can improve task awareness and decreases cognitive load (Fig. 9). As an example, Huang et al. (2018) evaluated the effectiveness of sharing hand gestures and

Collaborative Environments for Augmented and Virtual Reality Applications, Fig. 9 An example of a virtual environment in an industrial context experienced through a VR headset. Photo by XR Expo on Unsplash

sketches made by a remote user to help a local unskilled operator. The two users interact by using an immersive VR device (remote operator) and a handheld interface (local operator) connected on the same Local Area Network. The main results show that by sharing both hand gestures and sketches the local users can complete the tasks with less time with respect to sharing only hand gestures. The independence of the view has been also deeply investigated. The remote user could visualize the local scene by seeing the environment from the local user perspective (dependent view) or from arbitrary views (independent view), and some researchers have demonstrated the advantages of the independent view with respect to the dependent one (Kim et al. 2018).

- In the medical context, CEs can foster communication between patients and medical specialists. It is expected that medical costs will be increasingly reduced using effective CEs. Nonetheless, several important features, such as latency and tracking accuracy, have not been properly evaluated in this context yet. Similar to the industrial scenarios, by exploiting the visualization of a 3D environment, remote expert medical teams can provide instruction to local unskilled doctors during medical procedures. As an example, Sirilak et al. (Sirilak and Muneesawang 2018) proposed a remote, synchronous AR system to support local doctors during medical operations. The local doctor can visualize by a wearable AR device patients' data captured through dedicated sensors. At the same time, remote specialists can visualize the local scene captured by the cameras of the wearable devices allowing them to collaborate with the local doctors. Finally, the emulation of surgery operations executed in VR can be linked to the data visualization in AR (Fig. 10).

- CEs for tourism and cultural heritage scenarios have been also researched and analyzed. Usually, these systems are used to draw the attention of the users towards points or objects of interest; therefore, it becomes of primary importance providing effective spatial cues to make sure the users are not disoriented or get lost. A typical scenario involves a local AR user who is physically walking through an archaeological site or museum and a remote

guide who can add spatial virtual cues and instructions in the real environment (Fig. 11). Due to their wide adoption, handheld devices are still much more used in these scenarios although head-mounted displays are increasingly researched and studied. Chen Lee Swift et al. (2015) proposed a remote, synchronous system to support cave explorations. Local users can map the real cave creating a virtual reconstruction of the archeological site by using AR wearable devices. Specifically, a local user, wearing a Microsoft HoloLens device, produces a virtual representation of the cave whereas a remote user can either interact with a Skype call or he/she can add virtual annotations by means of a tablet device, thus fostering the cultural experience.

Collision Detection

Simena Dinas
Departamento de Electrónica y Ciencias de la Computación, Pontificia Universidad Javeriana Cali – Colombia, Cali, Valle, Colombia

Definition

Collision detection is the process of determining computationally if two or more objects intersect, the time, and the parts of the objects that are involved in the intersection.

Introduction

Collision detection (CD) concerns to determining *if* the intersection between a pair of objects happens, and after a positive answer, to determining *when*, and *where* it happens (Ericson 2005). *If* a pair of objects intersect must give information about the existence of the intersection, whereas *when* they intersect must give temporal information about the time of contact. Finally, *where* the objects intersect must give information about the area of each object that is involved in the intersection.

For applications on robotic and graphic computer areas, it is important to model and simulate the physics of the objects, thus, these areas have used highly CD approaches whereas, specific areas using it include physical-based, surgical, dynamic and cloth simulations, motion planning, molecular modeling, virtual environments, obstacle avoidance, virtual prototyping, virtual assembly, computer animation, among others (Tang et al. 2010; Wong 2011; Zhao et al. 2013; Moll et al. 2014; Du et al. 2015; Wang et al. 2018). Because of the computational complexity, CD is a bottleneck for several applications (Moll et al. 2014), especially, for real-time applications (Pabst et al. 2010; Dinas and Bañón 2015).

Classification of Collision Detection Approaches

CD problem can be classified mainly into four approaches: static, pseudodynamic, dynamic (Basch 1999), and kinetic. However, another division found in the literature is only based on static and dynamic approaches (Ericson 2005). In the static approach, the collision is queried in a particular object position; then, time and usually trajectories are not relevant; the object may change the position randomly, and, consequently, queries are independent (Weller 2013). This approach is used to refine and evaluate the performance time for CD algorithms; besides, the static CD is the first step of a collision detector (Arcila 2008).

Commonly, pseudo-dynamic CD approaches check static interference tests in short intervals of time; they extended the static CD by adding trajectories and times and applying motion (Dinas et al. 2010). In the literature, temporal coherence is the use of preview steps information in a collision detector. It takes advantage of small changes of the objects position to reduce calculations based on the similarity between consecutive motions.

Dynamic CD approaches take advantage of swept volumes to check the collision, and it depends on initial values. There are two types of initial information: the "a posteriori" in which the objects may have a trajectory to navigate through, then the time and the trajectory define the object motion. As a result, the collision is detected after it happens. In contrast, the "a priori" dynamic approach is able to predict the collision before it happens.

Pseudo-dynamic and dynamic approaches deal with oversampling and undersampling problems. Oversampling happens when there is a lot of resource spent into collision evaluations; as a result, there are unnecessary calculations. In contrast, undersampling tests use fewer resources than required to detect collisions; then, some

collisions get lost (Basch 1999). Finally, kinetic approaches take advantage of predicates and certificates functions to determine the CD on time.

A characterization introduced by Zhang et al. (2006) divides CD approaches into discrete, which checks statically collisions between moving objects based on discrete parameter intervals (Pabst et al. 2010; Zhao et al. 2013), and continuous which tries to determine the time of contact (ToC) as exactly as possible (Tang et al. 2010; Wong 2011; Du et al. 2015). Continuous CD is a problem highly explored; the most common techniques are the algebraic solution, the swept volume, the bisection, the Minkowsky sum, the conservative advancement, and the kinetic data structure approaches (Zhang et al. 2006; Tang et al. 2010; Du et al. 2015).

Collision Detection Phases

CD methods are commonly divided into two phases the broad-phase and the narrow-phase. (i) Broad-phase methods determines the pair of objects involved in a potential collision and (ii) narrow-phase methods check exact collision for every pair identified as suspected to be in a collision by the broad-phase (Avril et al. 2014; Wang et al. 2018). Moreover, potential collisions identified in broad-phase are not always collisions; narrow-phase checked the existence of collision.

Broad-phase avoids highly expensive computations for faraway bodies (Weller 2013). An all-pair test or a brute force method calculates exhaustively the collision between each pair of objects.

Narrow-phase checks each pair for intersection between pairs involved selected as potential colliders in the broad-phase (Weller 2013; Avril et al. 2014). Convex objects, spatial partitioning, and bounding volume hierarchies are the most important narrow-phase techniques (Wang et al. 2018). Bounding volume hierarchies are widely used in the literature. The three requirements for bounding volume hierarchies are: (i) each level in the hierarchy represents a tighter fit than its parents, (ii) a set of child nodes in the hierarchy depicts the same part of the object covered by its parent node, and (iii) the bounding volume should fit the original node as tightly as possible with a high degree of accuracy for the original model. However, two opposite criteria that guide the selection of bounding volumes are: they should be as tight as possible, and the intersection test for two of them should be as efficient as possible (Nguyen 2006).

Collision Detection Objects

According to the changes on the objects after the collision, the methods can be classified into two categories: rigid-body models, which do not change after colliding (Tang et al. 2013), and deformable models or soft-bodies, which change after colliding (Tang et al. 2010; He et al. 2015). By exploiting the temporal coherence, models can be deformable along the time, even though they do not collide with others, for instance, animated objects like animals and people, cloth, among others. The collision that involves soft bodies and rigid bodies usually calculates the penetration depth and the area of collision of the objects (Zhao et al. 2013).

Synonyms

BCI; Brain Computer Interface; Color detection; EEG signal

Definitions

Color plays a critical role in information delivery in this vivid world. Capable of detecting imaginary colors can extend and enhance the current business model as well as the entertainment areas. In order to efficiently determine the imaginary color, essential knowledge of EEG signals, classification of the signals, and how to handle these signals are briefly discussed in this article. BCI applications are mainly divided into three categories: active BCI, reactive BCI, and passive BCI. In these days, most research purpose devices are noninvasive BCIs. EEG signals are commonly considered by four primary bands that carry different information. It is necessary to denoise the captured brainwaves prior to analysis and processing, Linear filter, Bandpass filter, and Independent Component Analysis, three common approaches of denoising are reviewed. Feature extraction and classification methods of brain signals are briefly introduced with former experiment examples. Finally, advantages and adoption preferences of methods are discussed

functionally. This article aims to provide a relatively comprehensive walkthrough of basic knowledge of brain signal processing towards detection of imaginary colors.

Introduction

BCI is generally referred to Brain Computer Interface or Brian Computer Inter-action, which enrich the communication method as well as the information delivery between human-being and machine. Brain signals are captured through BCI devices and then transferred to computer for analysis and processing. BCI devices are mainly divided into two categories: invasive BCI devices are directly implanted into people's brain and medically targeting restoration of fundamental functionality; noninvasive BCI devices are easy to wear and widely used in various applications. Noninvasive BCI devices avoid the surgery risk and are relatively portable, headsets such as Emotiv EPOC+ and Neurosky MindWave are popular in researchers. However, the draw-back of being external device is the relatively poor effectiveness of signal acquirement compared to invasive BCI devices. There are many particularly interesting, entertaining wearables such as the "necomimi" project (the Necomimi Emotion Con-trolled Brainwave Cat Ears Headband), where the headset has two catlike ears that are programmed to wave based on the wearer's emotion that evaluated through the brain signals captured from the brain wave sensor integrated into the headset (Kulkarni and Bairagi 2018).

BCI applications have been deployed into various aspects of world such as home-automation, lie-detection, brain fingerprinting, trust assessment, sleep stage recognition, disease observation, and neurorehabilitation. BCI applications could be macroscopically divided into three main types that differ in the primary characteristics of BCI-interactive models in various applications. Interaction and design models are hence differentiated in numerous researches in the BCI field.

Active BCI: An active BCI application produces its final output from brain activity which is directly consciously controlled by the user such as using mental command, thinking to control hands, and execute actions. Such type of brain activity is independent from external events to control a BCI-application.

Reactive BCI: A reactive BCI application produces its final output from brain activity arising in reaction to external stimuli such as viewing pictures or particular objects. Such type of brain activity is indirectly modulated or reacted by non-subjective consciousness of user to control a BCI-application.

Passive BCI: A passive BCI application produces its outputs by analyzing arbitrary brain activity without specific events for enriching a human-computer interaction with implicit information that user may not aware from the subjective consciousness such as the degree of engagement and relaxing status.

Color has an important role in digital society to present additional information to contents that needs emphasizing and have specific intentions. People coming from different backgrounds and countries could have various understanding on particular colors but commons can be observed. Three primary colors, red, green, and blue are usually applied in color-related researches. These three colors are deemed as the ideal primaries for additive color mixing with the lighting sources (Rossing and Chiaverina 1999). Red associates with energy, danger, strength, power, determination and passion, desire, and love. Green denotes the nature which usually symbolizes growth, harmony, freshness, and passing. Blue is the color of the sky and sea and commonly associated with depth and stability as well as safety. Color detection models are mostly categorized into reactive BCI applications as most applications require participants to be stimulated by a number of colors in order to achieve initial calibrations before the actual usages. Capability of recognizing colors through brain signals could enable researchers to understand deeper and further flexibilities available to developers.

Methods

EEG Overview

Noninvasive Brain Computer Interfaces are usually based on the Electroencephalography (EEG), the electrophysiological monitoring approach to record electrical activity, the communications happened between brain neurons inside human's brain. Extensive researches undergoing in medication and science have the root from Liverpool in 1875, a physician practicing, Richard Caton who demonstrated the presence of electrical currents in the brain (Caton 1875); the first EEG recording of human is achieved by the German physiologist and psychiatrist Hans Berger who afterwards extended the research and invented the electroencephalogram which is described as one of the most outstanding advancement in the history of clinical neurology (Haas 2003).

Unlike invasive EEG devices that directly planted into the brain to monitor brain activities along with a great resolution, noninvasive EEG devices need external auxiliary tools to monitor the brain. Electrodes are introduced in noninvasive EEG devices to equip on the scalp: vertically beginning from the direction of nasion, sunken part of the nose (between eyes, above the bridge of the nose) to inion, the prominent bone at the back of the head; and horizontally from the left ear lobe to the right (Oude 2007).

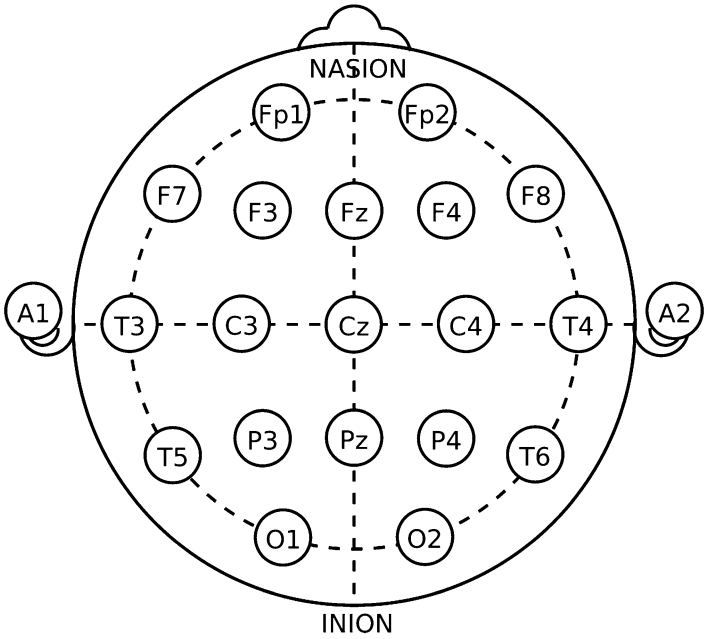
The operation that an electrode captures the electrical activity in brain is called an EEG channel that typical EEG systems have only a few channels available to use. More electrodes denote a clear signal that can be observed from the brain activities. EEG devices are usually equipped up to 256 channels and electrode placement on the head has a formal standard, namely, the International 10/20 system that usually shortened to 10/20 system. The 10/20 system is the standard electrode location method to acquire EEG data and is utilized by most of current databases (Soutar 2014).

The standard placement system, the 10/20 system, suggests the definition of exact position of electrode placement and assignment of symbols that denotes particular electrodes to access particular part of brainwaves that can be monitored from various part of the brain. It defines the placement of electrodes that should be adhered to the calculated distance between nasion and inion for a particular person. The separation of electrode placement is normally defined by particular EEG device depending on the number of electrodes available. In general, a 10% or 20% of the reference distance is utilized, and in circumstances that a greater granularity (resolution in other words) is required, the placement distance of electrodes are further shrink to 10% (Chong et al. 2007).

Usually a greater granularity demands more electrodes to be set up into the cluster that separated on the scalp. A typical prototype of 10/20 placement system is shown in Fig. 1. The nomenclature of electrodes that placed by the 10/20 placement system has particular rules that corresponds to identifications of area or regions of brain that electrodes is reading from such as: Frontalpolar (Fp), Frontal (F), Temporal (T), Occipital (O), and Central (C) (Chong et al. 2007). Specific rules are applied on the numbering measure of electrode placements: even numbers are assigned to the electrode places on the right side of the head and odd numbers are assigned to the left side. Each EEG channel presents different type of information of brain activities; sophisticated analysis of multiple channels is always necessary in order to achieve higher accuracy of classification of brain signals.

EEG Bands

There are many bands available to carry different part of information of brain-waves and the analysis of a particular band may differ depending on the researcher's final goal (Rasheed and Marini 2015). Conventional bands such as delta (< 4 Hz), theta (4–7 Hz), alpha (8–12 Hz), and beta (13–40 Hz) are usually considered as the primary frequency ranges. In the regards of the EEG captured data, the EEG is usually discussed in terms of rhythmic activity (the rhythm) and transients (the fluctuation of amplitude). Cerebral signals observed in the noninvasive EEG devices always state in the frequency range of 1–20 Hz where out of range usually denotes a nonstandard recording technique or it is deemed as artifactual. General



Color Detection Using Brain Computer Interface,
Fig. 1 Electrodes placement (Sjölie 2011)

observations of brainwaves are categorized in below.

Delta (<4 Hz): Delta waves were originally introduced in 1936 by Gray Walter, an English physiologist who acquired very slow and high-voltage potentials that were slower than formerly described wave patterns from the involved area of a patient who was undergoing neurosurgery for a malignant tumor (Marcuse et al. 2015). The characteristic of delta band aims at the highest in amplitude and has the slowest waves. It is usually found frontally in adults in slow-wave sleep and posteriorly in children. As the rule, delta waves are absent in wakeful adults, and in contrary, presence of delta waves during wakefulness implies cerebral dysfunction (Marcuse et al. 2015). Furthermore, delta waves are usually associated with the deepest levels of relaxation and restorative, healing sleep, in other words, adequate production of delta waves enhances the immune system, natural healing and restorative deep sleep (Abhang et al. 2016).

Theta (4–7 Hz): Theta rhythms are generally observed in the frontocentral areas of the brain in young children and are related to drowsiness or heightened emotion states (Scher 2018). Drowsiness arousal can produce theta waves that are observable in older children and adults as well as during meditation. Excess theta waves always de-note a number of clinical conditions, such as epilepsy, or abnormal activity of adults such as focal disturbance (Scher 2018). Additionally, theta waves are usually associated with relaxation, meditation, and creation states.

Alpha (8–12 Hz): The first recording of human EEG waves by Hans Berger is in the alpha range. It is observed in the occipital cortex, the posterior areas of both side of the head (Baars and Gage 2013). Higher amplitude always shows on the dominant side. Alpha waves usually relate to motor activities such as eye movements. Particularly, closing eyes with comfortableness raises the alpha waves and attenuates with eye opening and mental concentration (Bazanova and Vernon 2014). The alpha waves are also subject to age dynamics as the alpha rhythms in healthy subjects reduces associated with age in the interval from 7 to 80 years in terms of power which reaches the highest values around 20 years of age and slowly declines (Kropotov 2016).

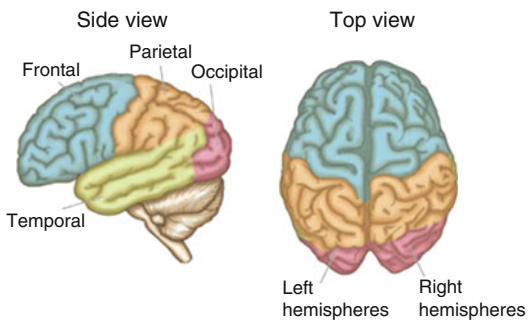
Beta (13–40 Hz): Beta waves are observable with increased possibility in frontal or central

regions of brains compared to posterior areas of the cortex (Kropotov 2010). Beta waves are high-frequency and low-amplitude brain waves in awaken sate and are produced associated with logical and conscious thinking, where production of adequate beta waves enhances concentration (Abhang et al. 2016). Active concentration, busy, active thinking leads to a lower amplitude beta wave, the beta one waves, the low beta waves (12–15 Hz); Mid-range beta waves are described as beta two waves associated with improved performance and anxiety; High beta waves are described as beta three waves associated with significant anxiety, paranoia, and high arousal (Ab-hang et al. 2016).

Brain Lobes and Functions

EEG signals are captured from various positions of the brain. It is critical to understand the brain functions of different cerebral cortices that each of which has important roles to composite the consciousness. The cerebrum dominates the most spaces of the human brain associated with complex brain functions among cogitations and activities. The cerebral cortex is divided into four lobes and two hemispheres which are shown in the Fig. 2.

Frontal Lobe: Frontal lobe is commonly considered as a synonym to the executive functions, utilizing the capacity of the frontal lobes to administrate and improve other cognitive processes more efficient through attention, to inhibit basic response in approaching a complex objective, abstraction and other mechanisms (Pressman and Rosen 2015). In actual, frontal lobes composite of a number of regions that participate various brain processes such as attention, memory, executive functions, insight and self-monitoring, language, and social and emotional functions (Pressman and Rosen 2015). Furthermore, common sense has theoretically different perceptions to the executive functions, are fundamentally classified as the abilities to retain and process objects not physically placed in the surrounding environment (Goldman-Rakic 1996). However, the functional organization of frontal cortex is still controversial where the primary theory proposes that frontal lobes are organized correspondingly to rostrocaudal axis to participate in the hierarchical cognitive control (Badre and Nee 2017). In summary, frontal lobe is functioning in cognition, problem solving and reasoning; development of motor skills; participation in speech; Impulse control; spontaneity; regulation of emotions; regulation of sexual urges; and planning (Abhang et al. 2016).



Color Detection Using Brain Computer Interface, Fig. 2 Brain lobes and hemispheres (Bermúdez 2014)

Parietal Lobe: Parietal lobe is commonly described with correlation to the sensory processing in the brain. It occupies approximately 20% of the cerebral cortex and is categorized into two primary regions, the somatosensory cortex and the posterior region of the parietal cortex which engages in various cognitive operations, especially involved in representations of spatial subjects (Behrmann and Shomstein 2009). Goldberg (2001) described five primary functions: the fundamental analysis of somatic sensation (such as touch, the limb positions, temperature perception); space measurements utilizing sensory modalities; the specification of spatial objects for the motor system; generation of attention; and the analysis of visual motions. In summary, parietal lobe is functioning in sensing pain, pressure, and touch; regulation and process of traditional five senses: vision, audition, gustation, olfaction, and somatosensation; movement and visual orientation; speech; visual perception and recognition; and cognition and process of intelligence (Abhang et al. 2016).

Occipital Lobe: The occipital lobe holds responsibility for visions primarily and is situated posteriorly to both the parietal and temporal lobes.

It is the smallest of the four lobes and it occupies approximately 12% of brain cortex; visual sensations are produced from the occipital lobe through direct electrical stimulations and damage to the occipital lobe can influence visions in different degrees depending on the location damaged and severity of the damage (Galetta 2017). Most of the knowledge of structural organization and processing mechanism of occipital lobe comes from the studies of macaque's occipital lobe which shares a certain degree of similarity with humans. In addition to the spatial specification of visual objects that are maintained in the occipital lobe, visual attributes such as local shape, motion, color, and depth are also extracted and organized (Braddick 2001). In summary, occipital lobe is functioning in visualspatial handling; movement, and color recognition (Abhang et al. 2016).

Temporal Lobe: Temporal lobe associates with perception and recognition, is the region where sound is processed, which regulates the auditory language and speech comprehensions (Baars and Gage 2013). Along with the frontal lobe, the temporal lobe functions significantly in humans, indicating the anatomical relationship of two areas towards acoustic, intelligence, and memory (Bellack and Hersen 1998). In summary, temporal lobe is functioning in management of long-term memories and handles new information, formation of visual and verbal memories, and interpretation of olfaction and audition (Abhang et al. 2016).

Pre-processing of Brainwaves

Captured brainwaves always contain further noises than the useful information. Pre-processing is usually necessary for clearing the noise, reduce the noise ratio of raw EEG signals as the captured raw signals are generally contaminated with irrelevant activities such as eye blinking and physically micro movements. Such activities are called artifacts, which can cause accuracy and efficiency issues in the system. During the recording and amplification period, main's electrical impulse, minor physical movements such as eye blinking or muscle movements and artifacts could interfere the captured data (Rasheed and Marini 2015). Artifacts can also be yielded by the problematic EEG equipment or the external interferences, such as radio waves and mobile phones. Pre-processing methods are commonly required prior to processing and analysis of the recordings. In the former experiment conducted with color detections, a number of methods were utilized to remove artifacts: visual inspection, linear filter, bandpass filter, and independent component analysis (ICA). For event-related potentials (ERP), applying visual inspection along with linear filter or band-pass filter at specific frequency can remove skin potentials at low-frequency bands and muscle and electrical noises at high-frequency bands. Visual inspection is usually necessary to manually remove undesirable segments of brain signals in a trial as the recordings may contain further instructions other than the valuable data, the potentials in recordings with color stimuli. In advanced environment, ICA is significant in removal of artifactual components such as muscle activity, eye blinks, and electrical noises (Delorme et al. 2007). Applying various methods to reduce artifacts could improve the rate of successful classifications, such as Phillips et al. (2015) applied Joint Approximate Diagonalization of Eigenmatrices (JADE) algorithm as the ICA and the classification accuracy shows an approximate 5% improvement over the 20 trials conducted during the experiment.

Feature Extraction

Feature extraction is to extract the adequate feature that is valuable in each single trial. Extensive ways are available to select different features, such as the simplest, calculating the peak in power spectrum, and calculating the mean of a set of trials. Abuhashish et al. (2014) concluded a number of common features are extracted: the value of the EEG signals largeness, band powers, power spectral density ideals, autoregressive and adaptive autoregressive parameters, time-frequency features, and inverse model-based features. Yu and Sim (2016) conducted an experiment that classifies the brainwaves captured during the simulation released by the specially made visual stimulator that manually created using an Arduino board and a couple of LEDs. They extracted N2 (N200, the negative-going

wave that peaks 200–350 ms after stimulus (Folstein and Van Petten 2008)), P3 (P300, occurs when people react to stimuli and surfaces as a positive deflection in voltage with a delay between stimulus and reaction ranging from 250 ms to 500 ms (Polich 2007)), and N4 (N400, the normal brain reactions to meaningful stimuli such as visual and auditory stimuli (Kutas and Federmeier (2000)) of ERP data and achieved classification rates ranging from 35.76% to 87.11%. Aclo et al. (2016) conducted similar experiments utilizing an LED screen monitor doing color stimuli, and Kurtosis was found to be the most significant feature in alpha and beta bands for classification of colors.

Classification

Numerous classification algorithms are available to deploy in different scenarios, such as Support Vector Machine (SVM), Artificial Neural Network (ANN), Multi-player Perceptron (MLP), Naïve Bayes (NB), k-Nearest Neighbor (k-NN), and K-fold Cross Validation. SVM and ANN are the common approaches adopted in researches related to classification of imaginary colors and are briefed in below:

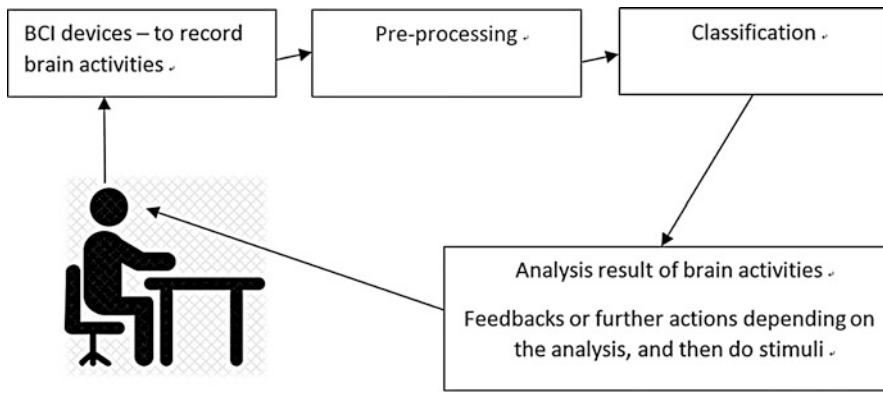
Support Vector Machine (SVM): SVM was introduced in the late 1990s and has been adopted in many engineering-related applications (Gholami and Fakhari 2017). SVM is one of the machine learning, non-probabilistic approach utilizing a linear classifier to categories data into two types and has an overall good performance (Peter et al. 2019).

Artificial Neural Network (ANN): ANN is the computational technique, one of the machine-learning approaches trying to learn the behavior of the brain signals. In analogy, ANN utilizes a large set of computational units, the artificial neurons to simulate brain neurons.

Classification Performance: Classification rate can also be influenced by different combination of selected channels. Selecting one or a few appropriate channels can improve efficiency and performance of the application. Such as Yu and Sim (2016) found that channel T7 and F4 are robust electrodes to classify color imaginations and Aprilianty and Purwanegara (2016) found that F3 and F4 channels are having a better classification rate. Additionally, Yu and Sim (2016) found that applying ANN without LDA can bring an approximate 10% improvement in the classification rate.

A Typical BCI Research Model

A simple, typical BCI application model is described in the Fig. 3. Most of the stimuli researches share commons in basic modelling of the application and can differ based on the final purpose. This model can be applied in the color stimuli experiments, and the devices utilized to present colors can be selected from a large group of different categories, such as the simplest one, computer monitors or some specifically made



BCI devices – to record brain activities
Pre-processing
Classification
Analysis result of brain activities
Feedbacks or further actions depending on the analysis, and then do stimuli

Color Detection Using Brain Computer Interface, Fig. 3 A simple, typical BCI application model

LED devices to represent various colors, achieved in Yu and Sim (2016)'s research. Researchers have the initiative to select particular colors that can be represented by different devices. According to the specifications designed, the final results of different researches could show a certain degree of deviation when the preciseness is critical.

In the color stimuli experiments, a number of participants will be asked to re-main quiet and comfortable before starting the EEG recording sessions. Generally, the device represents a particular color for a few seconds and the brainwaves of participant will be captured and recorded by the BCI devices during each session. The recording sessions will then be pre-processed before apply further analysis and actions. After filtering, denoising, and feature extraction, all recording sessions will be converted into small pieces. These small pieces will then be analyzed and classified into a number of different classes. Based on the analysis and classification result, further actions can be taken and different stimuli scenario can be used to expand the recording library. Usually, a larger library of recording sessions with various scenarios will increase the accuracy and value of the final results.

Discussion

There are numerous feasible approaches to implement the theoretical prescription described in the method section into working solutions, such as BCILab and EEGLab (Delorme and Makeig 2004), two available Matlab applications that greatly simplified the data analysis of brain signals with graphical interfaces. Regarding preprocessing of brainwaves, although ICA can achieve a better result of removing noises in the trials comparing to applying linear filter or bandpass filter, the draw-back is the performance issue as it takes more computational power to produce the processed trial. In the applications that require responsiveness and are designed for portable devices with limited processing power will prone to utilize the other two methods to denoise the signals. In the feature selection part, the experiments con-ducted by former researchers are limited and there are potentials to explore new features. Finally, both of SVM and ANN are commonly adopted techniques, have the same concept using linear learning model for pattern recognition, and the main difference is the way nonlinear data is classified (Ren 2012). Even though some studies suggest SVM has a better performance than ANN, the average accuracy achieved is around 80% and the accuracy decreases dramatically when the training trials are imbalanced.

Color classification can be used in various scenarios of world. For example, in the enhancement of the existing selling models, customers could simply think to get the right color of a desired clothes or items. It can certainly improve the efficiency of shopping as well as reduce the pressure caused on shop assistants during the peak hours. However, BCI devices are still relatively complicated to be equipped and prone to be influenced by the interferences such as radio waves. The cost of device maintenance will also be increased and new technical positions are possibly critical to be fulfilled. Capability of determining the colors imagined can be also used in BCI games to map further actions that cannot be performed by human in the real world such as flying. In the case of mapping a single color to a single action in the game, the traditional gaming can be flawlessly shifted over to the BCI gaming where a higher level of concentration and reaction of gamer could lead to a better result. Furthermore, the research conducted by Abuhashish (2015) also proposed the same idea of eliminating conventional models of interaction between human and computer graphics by analyzing the brain signals to map emotions into the virtual world. Particularly, Abuhashish et al. (2015) constructed the models of mapping human emotions with virtual 3D characters by utilizing Higuchi algorithm to extract human emotions and then to synchronize with in-screen characters.

Conclusion

This article provided a relatively comprehensive overview on the basics of BCI, EEG, and brain functions and a number of feasible approaches of pre-process, extract, and classification in order to

detect imaginary colors. Various terms used in neuroscience are explained and some fundamental knowledge of dealing with brain is briefly introduced. A number of signal pre-processing methods: linear filter, bandpass filter, and ICA and classification methods: SVM and ANN are briefly discussed. Examples of how selling and gaming models can be benefitted with capability of determining imagined colors are finally introduced.

Synonyms

Bit; Byte; Color; Color primaries; File format; Pixel; RGB

Definitions

Color (in computing) is represented by three values: red, green, and blue which are often also referred to as RGB.

Pixel is the basic, smallest and square-shaped element of a digital image.

Bit is a binary value and the basic unit of computational data.

Byte is the smallest unit of digital information in computational processing and storage.

File format is the structure with specifications on how the information to be organized and displayed.

Pixel and Path

The rapid development of computing and imaging encourages digital creations. Creative software can be largely divided into two types: one for image manipulation and the other for image fabrication.

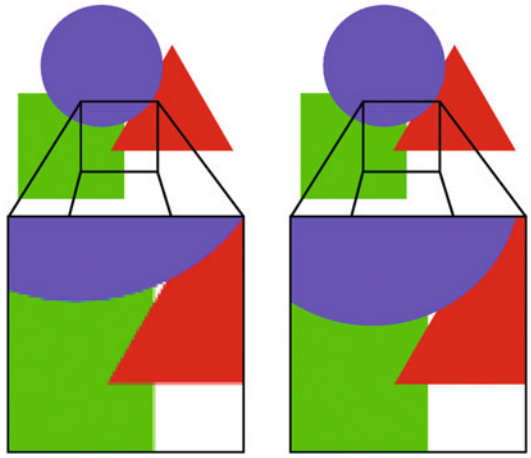
Image manipulation refers to the changing or enhancing the appearance of existing images. Those images are often regarded as raster images with pixels as their basic composition. Image fabrication is oriented for generating original illustrations. The approach is more often vector-based, in which lines and shapes are represented by equations. The basic unit of vector images is called path.

One significant distinction between raster and vector images is the fineness or smoothness in terms of image quality when the magnification

reaches a certain level (see Fig. 1). The quality of vector images is not constrained by scale.

Another distinction is the requirement of processing and storage capacities. Raster images tend to take up much more space than vector images.

Although vector images are more efficient, both in fidelity and space, than raster images, there is still a dominance on the use of raster images. This can be explained by the imaging resources, including software compatibility and file formats. Imaging devices render raster images, which include also photographs (see Fig. 2), and, thus, correspondingly majority of the file formats support raster images.

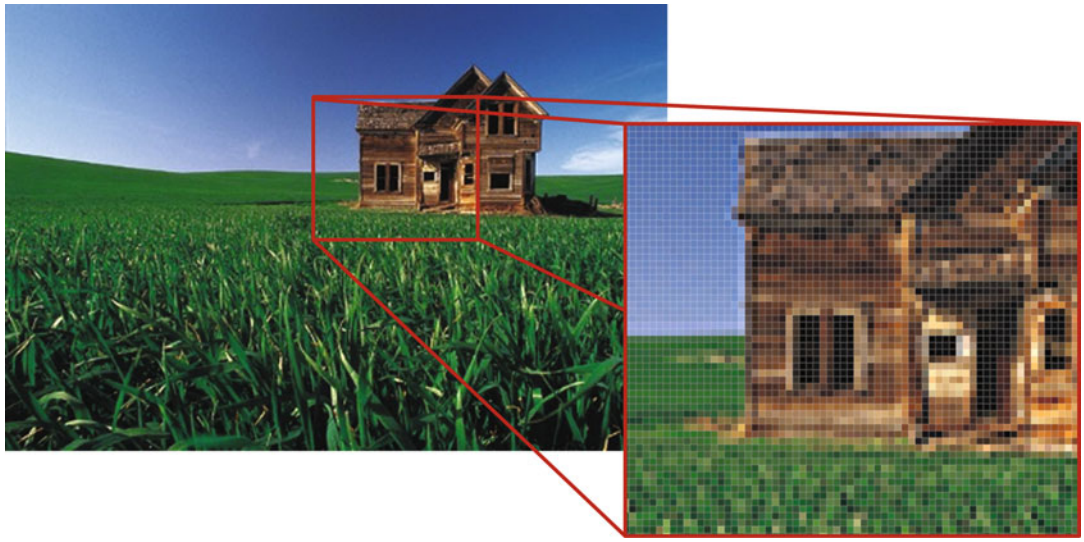


Color: Pixels, Bits, and Bytes, Fig. 1 Demonstrating the appearance of a raster image (top left) with a vector image (top right) at certain magnifying level (bottom)

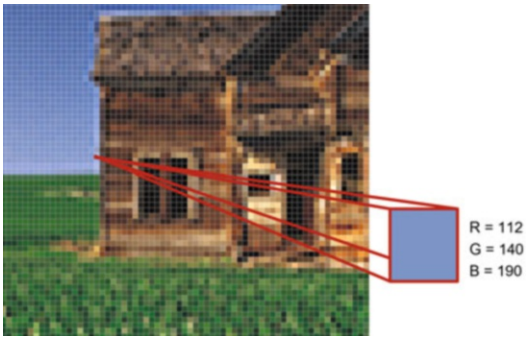
Pixel and RGB

Computer adopts the binary system, 2^x, to process information, and its basic unit is called bit. With the binary system, a bit can be only one of the two values: 0 or 1. That said, two bits (2^2) allow four possible conditions: [00], [01], [10], and [11]. Since the first condition is always regarded as 0, two bits represent numbers between 0 and 3.

As of today, majority of computers are 8-bit (2^8) devices, and thus they can offer 256 conditions ranging from 0 to 255. These conditions allow fine grayscale tonal variations for images. Color images are typically represented by 24-bit with 8-bit per each of the red (R), green (G), and blue (B) primaries. That said, a typical computer is capable to display images with approximately 16.7 million unique colors (Fig. 3).



Color: Pixels, Bits, and Bytes, Fig. 2 The basic unit of a raster image is pixel. A raster image consists of an array of pixels. This example image has a total of 1,100 (width) by 741 (height) pixels. These numbers also represent the image size



Color: Pixels, Bits, and Bytes, Fig. 3 Each pixel has a color that is defined by the red (R), green (G), and blue (B) values

Pixel and Byte

Image file size determines how much computing storage space a file is required. The basic unit of any file size is byte (B). There are also units such as kilobyte (KB), megabyte (MB), gigabyte (GB), and terabyte (TB) to indicate the larger file sizes. See Table 1.

Every 8-bit, which is 256 values, occupies one byte of computing storage space. Therefore, simply one RGB color pixel will require three bytes of computing storage space. Image file size varies, but it is not uncommon to see color image files of several megabytes.

Pixel and File Format

Practically, for websites and apps, several megabytes for each color image could take up significant time to load or download. To allow better efficiency, there are several file formats for users to opt for depending on the intended applications.

Some commonly used file formats for raster images are TIFF (.tiff or .tif), JPEG (.jpeg or .jpg.), and GIF (.gif). TIFF is often recommended for images that require high quality and raw data being preserved. JPEG can compress images by removing certain selected data of the file. It is a popular alternative to TIFF files, especially since it has the flexibility to allow different levels (e.g., 5% or 20%) of data removal. This provides an advantage for images that contain significant saturated colors and smooth gradations, such as sceneries and portraits. For graphical images, GIF file format is preferable since it stores only 8-bit per pixel. That said, a maximum of 256 unique colors which are seen to be sufficient for simple graphics, for instance, logos, graphs, and charts.

Color: Pixels, Bits, and Bytes, Table 1 File sizes – their units and conversions

1,024 bytes (B)	= 1 kilobyte (KB)
1,024 kilobytes (KB)	= 1 kilobyte (MB)
1,024 megabytes (MB)	= 1 gigabyte (GB)
1,024 gigabytes (GB)	= 1 terabyte (TB)

A note to the approach of JPEG file format on reducing file size by removing data is its understanding on the characteristics of pixels in images and the limitations of the human eye. In particular, some pixel values are more common than others, and neighboring pixels have similar colors. Also, very importantly, the fact that small color changes are perceived less accurately by the human eye than small changes in brightness. Thus, the selection of data that to remain and to remove is prioritized by minimum perceptual differences between the original and compressed images.

Definition

Non-photorealistic rendering (NPR) is a topic under computer graphics trying to achieve some level of stylization in 3D with the use of geometry, lighting, shading, and special effects. Authors are specializing in recreating the aesthetics of comic arts in video games via implementing the research already done in the area and also adding new research topics.

Introduction

Comic art stylization characteristics include toon shading, outlines, line art, hatching, and inner lines. The study of authors started with a literature review and implementing some of the real-time-related works to unreal engine. Unreal engine has been chosen mainly for its rendering quality, and

Comic Arts in Games, Asset Production, and Rendering, Fig. 3 Character with handmade line art texture

the ease of access to the source code if any change in the renderer is required to create the desired effects.

Hatching Shading Method and Line Art

Comic book art often uses different hatching techniques unique to its artist. Our goal was to minimize the texturing efforts in video game production pipeline. After trying different methods, the tonal art map pattern introduced in real-time hatching (Praun et al. 2001) seemed like the best option for creating seamless hatching patterns. Unfortunately, it didn't match the desired quality in the case of a repeated use especially on flat surfaces. We decided to limit the use of hatching shading on background organic objects.

The desired effect is achieved not by implementing a hatching shading in real time but

Comic Arts in Games, Asset Production, and Rendering, Fig. 8 Screenshot from Nowhere Studios upcoming game Dan Black where line art texture, distortion on UV, smoothed toon shading, and outlines have been used

by using a handmade line art texture drawn especially on the parts suggested by the ambient occlusion map by an artist.

Furthermore, the stylization of inner lines on hard surface models is achieved by adding a distortion on the UV outlines. This is a very similar technique to the one used in WYSIWYG NPR: Drawing Strokes Directly on 3D Models (Kalnins et al. 2002). This can be done either real time because the additional cost to GPU is negligible or while baking the texture so it can be modified manually if necessary. As UV outlines can be detected using an edge detection, the distortion process doesn't require any effort from the artist.

Outlines

Outlines are an important part of comic art. An edge detection algorithm is used to draw outlines. Edge detection is a post process; therefore, all of the methods create artifacts on their own. It is not possible to perfectly distinguish the object in the front from the background every time unless an inverted hull method introduced by "Guilty Gear X'rd technical presentation" (Motomura 2015) is used. The inverted hull requires the geometry to be drawn a second time; therefore, it is more costly.

Our edge detection draws the line to the pixel outside of the object, thus creating a proper silhouette of the object. The distance of the object from the background and the distance between the object and the camera are reflected in thickness and color of the line drawn.

Also inlines are drawn with a lighter line color similar to the technique used in suggestive contours for conveying shape (DeCarlo et al. 2003).

Comic book artists also consider lighting and geometry of the object while drawing the outline. This is a further research area for NPR.

The outline color can also reflect the color of the light source enlightening the object or it can be used as a second outline layer.

Toon Shader

Most art directors use toon shader to create paperlike characteristic. In video games, it is mostly difficult to achieve a good looking toon shader because of polycount limits. Hard transition between toon shading levels often gives away the low-poly geometry of objects. One solution to the problem is editing the normals of the model, but it requires time and effort. Our solution was to use smooth transition between toon shading levels.

Conclusion and Possible Exploration Topics

There are many further research topics including a better hatching pattern and technique, possibly using a deep learning methodology to analyze different comic art styles; an outline method reflecting light intensity and geometry; and a solution for easily editing the normal maps for better looking toon shading.

Comic art is one of the many possible traditional art styles one might try to imitate in 3D. Painting methods such as water painting, oil on canvas and many more, and also all the art movements, these techniques have been used with provide a very rich soil for non-photorealistic rendering research.

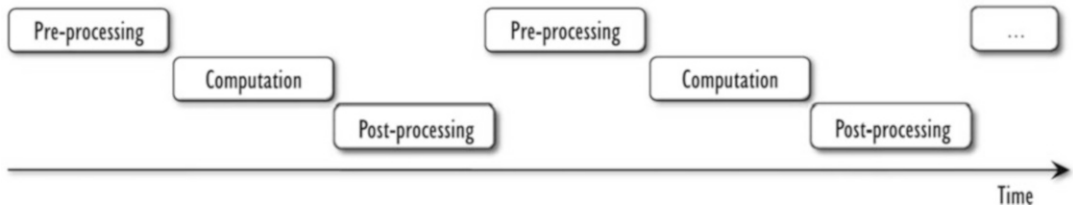
Definitions

Computational steering	is the practice of manually intervening with an otherwise autonomous computational process in order to change its outcome.
Computational fluid dynamics (CFD)	is the prediction of fluid flow by numerical methods.
In situ *visualization*	refers to the visualization of result data at runtime.

Introduction

Most computational fluid dynamics (CFD) simulations require massive computational power, which is usually provided by traditional high-performance computing (HPC) environments. Often, simulations are executed on a massive number of CPU cores (<check>O</check> (1000)) that are hosted in a remote supercomputing center or an in-house supercomputing facility. Due to several limitations of HPC environments, the majority of present CFD simulations are usually executed non-interactively, although interactivity of the simulation process is highly appreciated by scientists and engineers.

In this entry, different approaches for interactive CFD simulations are briefly reviewed. As



Computational Steering for Computational Fluid Dynamics, Fig. 1 Traditional CFD process chain (Linxweiler et al. 2011)

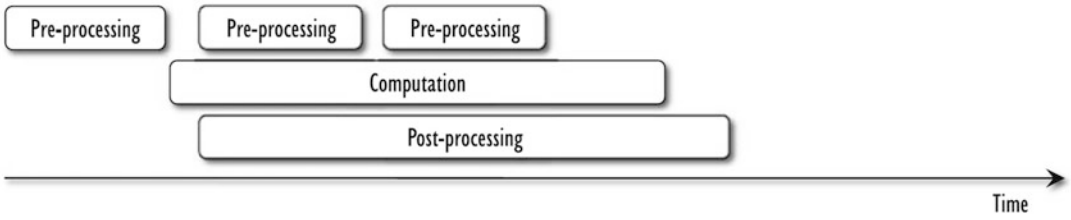
opposed to remote rendering solutions, where data to render is pulled over a connection to remote rendering stations, a recent trend is to harness the parallel computational power of locally available many-core CPUs, graphics processing units (GPUs), or mobile devices for general-purpose applications. Starting from the state of the art in conventional CFD simulations, this entry focuses on hardware resources that are available *on the desktop* and *in the palm of your hand* as a basis for computational steering.

State of the Art in CFD Analysis

Traditionally, CFD analyses are done in a cyclic sequence of independent steps (Fig. 1). The simulation is usually set up in a preprocessing phase by defining the geometry of the flow domain as well as the initial and boundary conditions. After that, the calculation is carried out for a fixed number of time steps. As CFD simulations are computationally intensive, they are usually executed on high-performance systems. In such high-performance computing environments, the job is typically submitted to a queuing system and is not executed until the needed resources become available. The simulation may run for hours, days, or even longer until in the end the results are stored on a file system. To conduct post-processing, this data is often transferred to the users' workstation to evaluate the simulation and identify errors or possible modifications to model parameters that will be applied in a subsequent iteration. The whole process chain is illustrated in Fig. 1.

For each adaptation that is to be made to the computation, the whole process has to be repeated. User interaction is obviously rather limited and takes place exclusively during the preprocessing/modeling phase. Not surprisingly, it is a long-term wish of scientists and engineers to closely interact with their simulations while they are running. Since the influential report of the US National Science Foundation (NSF) in 1987 (McCormick et al. 1987), new forms of scientific visualization have evolved that are quite different from traditional post-processing. The approach commonly referred to as *computational steering* has been the subject of widespread interest in the scientific CFD community. The name goes back to one of the first applications of interactivity demonstrated by Marshall et al. (1990) who presented an interactive simulation of a turbulence model using a simulation of Lake Erie. In the following years, major contributions to the development of the computational steering paradigm by Liere, Mulder, and van Wijk (Van Liere and Van Wijk 1996; van Liere and Mulder 1997; van Liere et al. 1997; Mulder et al. 1999; Mulder and van Wijk 1995; Van Wijk et al. 1997; Van Wijk and Van Liere 1997) as well as Johnson and Parker (Johnson et al. 1999; Johnson and Parker 1994; Parker et al. 1997a; Parker and Johnson 1995; Parker et al. 1997b, c) are recognized.

A first step to more interaction with the simulation is the so-called *tracking* (Marshall et al. 1990) approach, which is sometimes also called *monitoring* (Hart and Kraemer 1999). After each time step, intermediate results are sent to the visualization pipeline for analysis. This enables the scientist to analyze the results in an early stage of the simulation to stop and restart the simulation when required. The next step is



Computational Steering for Computational Fluid Dynamics, Fig. 2 Pipeline of computational steering (Linxweiler et al. 2011)

computational steering which goes a lot further. According to van Liere et al. (1997), it can be considered as the ultimate goal of interactive computing. Mulder and others define computational steering as interactive control over a computational process during execution (Mulder et al. 1999). As such, computational steering closes the loop in that scientists and engineers can respond to the results immediately by interactively changing the setup of the simulation without the need to restart the whole process. As changes to parameters become more instantaneous, the cause-effect relationship becomes more obvious so that scientists can develop an intuition regarding the effect of a parameter, detect bugs, or deepen their understanding of the physics or the algorithms of the considered problem (Parker and Johnson 1995). With computational steering, "What if?" questions can be answered more efficiently and therefore guide the investigation at runtime (Geist II et al. 1996). This leads to a significant increase in productivity and a vast reduction of the time between the generation of the results and exploration. Accordingly, the timeline of the computational steering pipeline can be summarized as depicted in Fig. 2. In addition to efficiency, computational steering also stimulates communication and discussion within engineering teams by providing immediate visual representation of the model and results (Van Wijk et al. 1997). These benefits make computational steering an important tool, especially for rapid prototyping and debugging, but also add value in other areas, e.g., for teaching (Linxweiler et al. 2007; Glessmer and Janßen 2017).

Conventional CPU-Based Approaches

Although the advantages of computational steering are obvious, its application in CFD, as well as other sciences, is still rare (Pickles et al. 2005; Wenisch et al. 2005; Wright et al. 2010; Janßen and Bindick 2019). There are various reasons for this, more often related to integration with traditional HPC systems. First and foremost, the development of a computational steering system is a complex task, as it requires the integration of multiple disciplines such as physics, numerical methods, user interface design, 3D graphics, and HPC (Parker et al. 1997c; Van Wijk et al. 1997; Linxweiler et al. 2011). Furthermore, HPC environments are traditionally not set up for interactive usage. Instead, the resources are remote to the user and typically managed by a queuing system. Computational steering violates many of the assumptions on which resource management systems rely. Therefore most site managers believe that interactivity wastes CPU cycles (Johnson et al. 1999). As a consequence most research, as well as commercial CFD codes, do not support interaction. The exceptions are, e.g., Kühner (2003), who demonstrated a 3D virtual wind tunnel, which combines an HPC system running the CFD simulation with a virtual reality system for facilitating exploration and handling user interaction. The application allows for dynamic adjustment of scalar parameters as well as manipulation of primitive geometries during execution. Based on this work, Wenisch (2008) presented a simulation of a ventilation system for operating theaters which also works with complex geometries. In cooperation with Borrmann (Borrmann 2007; Borrmann et al. 2006), this application was

extended to allow for collaborative exploration of the simulation results by multiple distributed users.

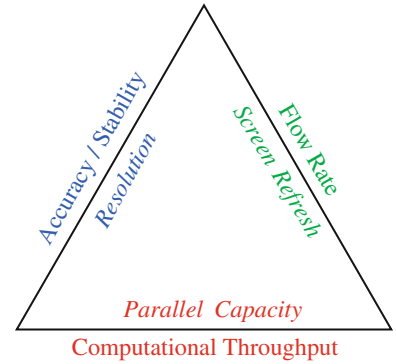
How to Measure Interactivity

For interactive simulations, it is essential that developers maintain awareness of the interplay between the perceived rate of flow to a user, the accuracy/stability of a calculation, and the computational throughput. These are the key qualities of an interactive simulation as discussed in Harwood and Revell (2018) and Harwood (2018, 2019) and are controlled therein through configurable parameters. The accuracy and stability of the numerical solver are controlled by the simulation resolution, the perceived flow rate to the user through the refresh frequency of the visualization, and the computational throughput through the amount of parallel compute capacity used (c.f. Fig. 3).

As the accuracy increases, so does the resolution of the calculation. This puts increasing demands on computing resources, typically shrinking the time step size. Thus, more iterations need to be completed for the same amount of time to be simulated. At a fixed computational throughput, the simulation thus evolves slower, and the refresh rate may need adjusting to compensate.

The real-time ratio T_r (Harwood and Revell 2018) expresses the ratio of the time simulated to the time taken to simulate that time interval with $T_r = 1$ being the precise definition of a real-time simulation. This provides an improved measure of the capability of an interactive calculation compared to just examining throughput alone. However, even if a calculation is running at a real-time rate, the refresh rate controls how the flow is perceived by the user. Therefore, for interactivity, we need to consider all these parameters simultaneously as we discuss below.

Consider the following illustration: a simulation uses a $dt_{sim} = 0.01$ seconds. The throughput of the calculation is 50,000 grid cells every second based on our chosen compute device. The resolution of the calculation is such that we have a 2D domain 60×30 cells. This gives 1800 grid cells in the domain. Our compute device can then update the whole grid around 28 times each second. Each time step on our given compute device takes $dt_{wall} = 0.036$. Thus we have a $T_r = 0.01/0.036 = 0.28$. Therefore the simulation is running at 3.6x slower than real time. Increasing the resolution may increase the throughput (assuming resources have not been saturated). So doubling the resolution, if the device scales perfectly, would double the throughput to 100,000 cells every second. However, for some numerical methods, such as the lattice-Boltzmann method, to control errors and maintain stability, the time step would then need to be divided by four (Krüger et al. 2009). Thus, $dt_{wall} = 0.036$ still but $dt_{sim} = 0.0025$ and hence $T_r = 0.0025/0.036 = 0.07$. Hence, the ability to achieve true real-time performance is dependent on both suitable numerical methods and suitable hardware and cannot be achieved by one alone.



Computational Steering for Computational Fluid Dynamics, Fig. 3 The interplay between the perceived rate of flow to a user, the accuracy and stability of a calculation and the throughput of the solver are important for interactive applications

Real-time ratio just considers the performance at a computational level. A user of an interactive simulation is probably less interested in whether the simulation is strictly real time but more interested in whether they see a smooth, yet accurate and expressive, visualization of the data in situ. This forces us to consider other factors when defining performance. For simulations to be visualized smoothly in situ, it is widely accepted that we need a refresh rate of our display of at least 24 frames per second (FPS). Returning to the previous example, we would need to update our display every iteration, giving us a frame rate of

$28 > 24$ FPS. Based on the throughput, we have a maximum perceived flow scale of $u_p = 28$ cells per second – i.e., the rate at which information is passed through our grid, one cell at a time. If we have 60 cells across a 30 cm width screen, then this is a perceived physical flow rate of 0.14 m/s. Of course, this is an upper limit achieved by acoustics in most cases, and typically, flow features of interest will propagate much slower than this. We must be aware that structures of interest may then propagate too slowly for interactive applications. In these situations, our options are:

- Reduce refresh rate – encourage information to propagate more before updating the screen.
- Reduce the time step (resolution) – often difficult without introducing errors and instabilities in the numerical method.
- Increase the parallel capacity (throughput) – often limited by available computing resources.

As is discussed in Harwood (2019), as well as in our example above, the adjustment of any one of these parameters in the pursuit of more speed, a higher accuracy, or a smoother frame rate may have an adverse effect on another metric; thus, the pursuit of interactive simulations is almost always a delicate balancing act.

Using Mobile Devices for CFD

Mobile devices (phones and tablet computers) are perhaps uniquely placed for computational steering activities as user interaction with a mobile form factor is more convenient and intuitive. However, the use of mobile hardware for conducting CFD simulations of a degree of fidelity appropriate for engineering applications has been largely unexplored in the literature to date. Being able to perform *interactive* CFD simulations on mobile devices allows the development of portable, affordable simulation tools that can have a significant impact in engineering design as well as teaching and learning. The work of Harwood and Revell (Harwood and Revell (2017, 2018); Harwood 2019) explores the feasibility of developing performant fluid dynamics applications for mobile CPUs and GPUs. They develop interactive CFD simulations suitable for mobile devices and test their implementations for a range of problem sizes. In Harwood and Revell (2018), the authors implement their simulation software using the CUDA API and use a combination of software development kits to compile the application. The application successfully harnesses the mass parallelism and power efficiency of the GPU to be over 300x more efficient in terms of combined throughput and power consumption than the earlier CPU implementation (see Table 1). However, the work outlines the complexity at present in creating mobile applications which can efficiently leverage the raw power of mobile hardware.

Recent work (Harwood (2019)) has explored the use of multiple mobile devices running a distributed interactive simulation implemented using OpenGL ES compute shaders and Java sockets. Contained within an Android application, the work examines the role of communication strategy as well as refresh rate (termed render frequency f_R in the entry) on the performance of the simulation as discussed in section. The render frequency proved to be an influential factor in terms of overall computational throughput (Table) with the time to render the screen not insignificant when performed frequently. Furthermore, the restriction of OpenGL render threads to 60 FPS by the Android OS artificially limited the throughput. This is something that is universally applicable for general-purpose GPU computing

Computational Steering for Computational Fluid Dynamics, Table 1 Comparison between CPU and GPU implementations. (Data taken from Harwood and Revell 2018)

Measure	CPU (6-tasks)	GPU (3 warps block)
MLUPS	1.1	14.83
Memory usage (MB)	5.9	6.0
Energy/physical second ($kW\,h \times 10^{-3}$)	5.23	0.232
Real-time ratio (T_r)	0.0395	0.832

which makes use of OpenGL for its implementation (Fig. 4).

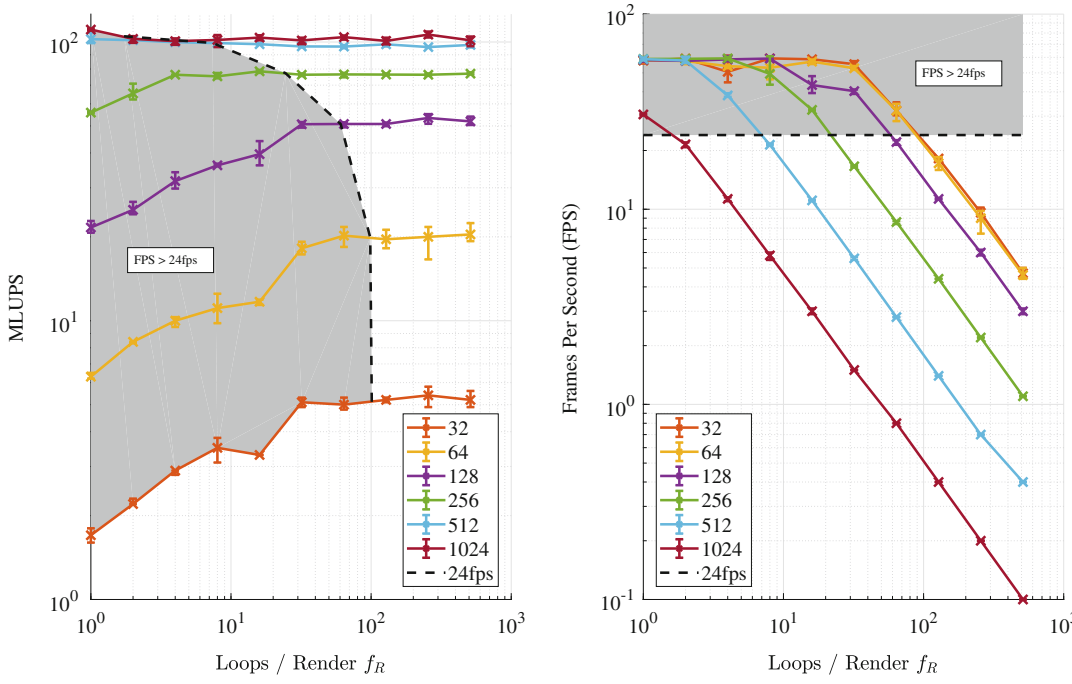
The time taken to conduct the 2D simulations over a wide range of resolutions, as expected, was significantly lower than the time taken to pass information between the networked devices. As such, the results of testing multiple devices (Fig. 5) illustrate two key findings: first, that with calculations at very high resolutions, it is difficult to hide this communication latency by adjusting the render frequency and perceptible stuttering in the visualization is inevitable. Second, the weak scaling of the algorithm across multiple devices is relatively efficient; thus, large-scale simulations across a cluster of mobile devices is likely to be possible.

Types of Mobile Application Development

Developing applications for mobile devices is a similar process to developing a desktop application with a user interface. However, the languages involved and tool chains used to build the software can vary dramatically from platform to platform and, thus, have a huge effect on the performance of the final application. Applications can be developed as native applications, web applications, and hybrid applications.

Native applications use the native languages and toolkits associated with a platform. On Android, codes written in Java and C++ using the Android SDK/NDK are forms of native development. On iOS, code is written in Swift or Objective-C. Native applications are fast and can leverage the full set of device capabilities through platform-specific APIs. They give the best user experience but at the expense of having to develop a different code base for every target platform.

Cross-platform applications can be developed using a higher-level suite of tools and then built for multiple platforms from the single, common code base. Web applications are the simplest approach to cross-platform development. Apps



(a) Performance in terms of MLUPS.

(b) Performance in terms of FPS.

Computational Steering for Computational Fluid Dynamics, Fig. 4 Performance of the current GLSL-based application for a combination of different resolutions n and render frequencies f_R. The target region for interactive simulations is 24 FPS and is indicated by the shaded regions. (Taken from Harwood 2019)

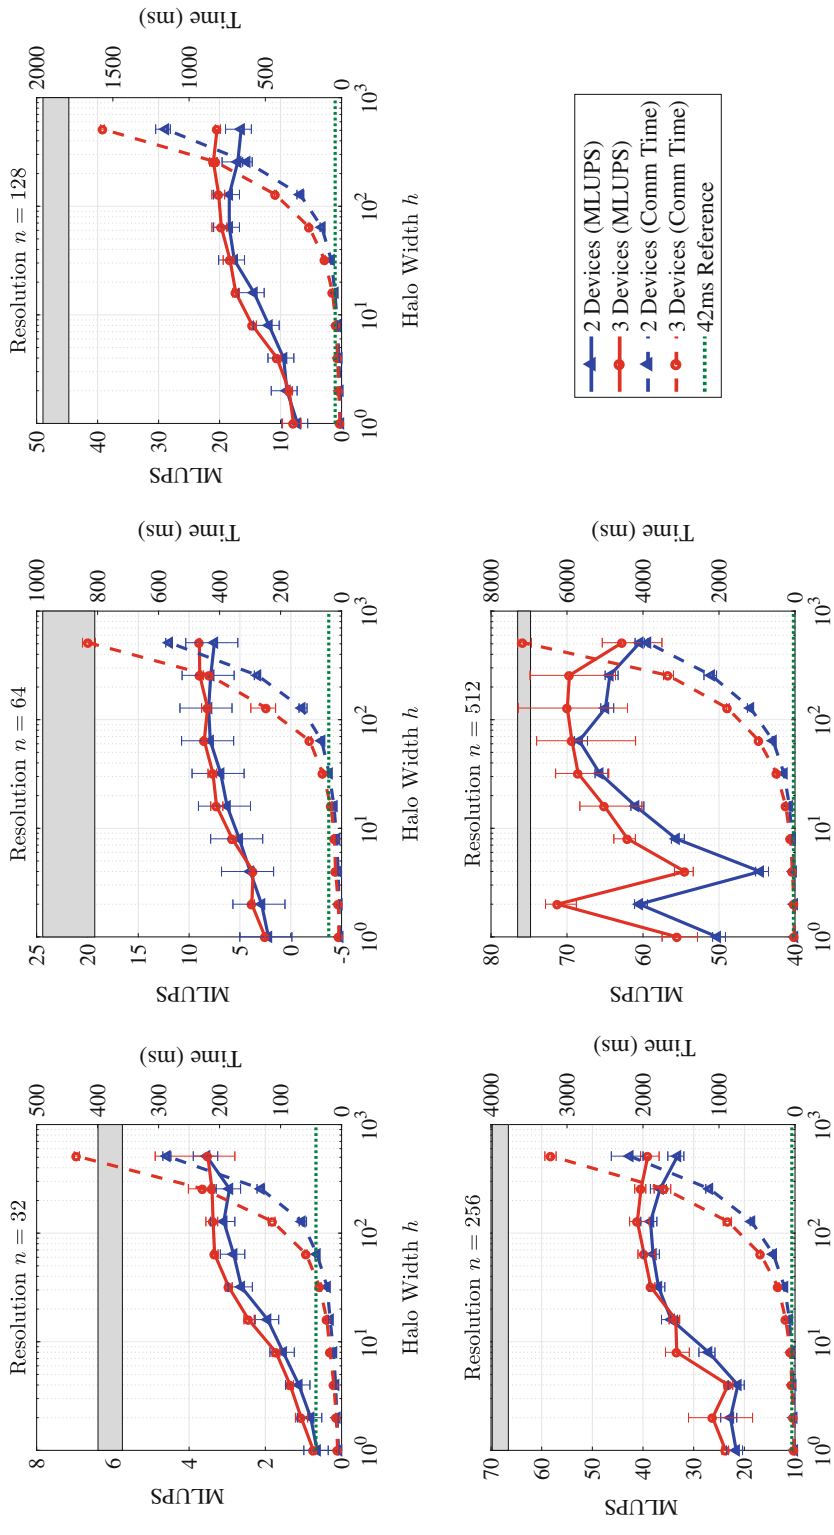


Fig. 5 Performance in million lattice updates per second (MLUPS) (left axis) and time taken to conduct communication (right axis) of the multi-device application. Shaded gray rectangles indicate the range of performance in MLUPS of the serial application run with the same configuration of resolution n and render frequency f_R. The green dotted line represents a time of 42 ms, the time of a single frame at 24 FPS. (Taken from Harwood 2019)

Computational Steering for Computational Fluid Dynamics,

C

are quicker to develop and easier to maintain but lack access to all device capabilities and are restricted in many respects by the web browser within which they run. Typically these applications are written using a platform agnostic API like the JavaScript, CSS, HTML, or combination of Cordova (PhoneGap).

Hybrid applications are usually a combination of the two approaches with some code written in a platform agnostic language leveraging a cross-platform API for most device functionality. UI elements are translated to native UI components, but some functionality may still need to be implemented on a per-platform basis.

For maximum performance, such as would be required by simulation applications, native approaches are recommended. The just-in-the compilation of the Java Virtual Machine on Android can further be circumvented by writing performance-critical parts of code in C++, precompiling these components as libraries using the Android NDK, and then linking these components to the Java application through the Java Native Interface (JNI). This approach is taken in Harwood and Revell (2018) to maximize performance while enabling the use of CUDA for a supported mobile GPU.

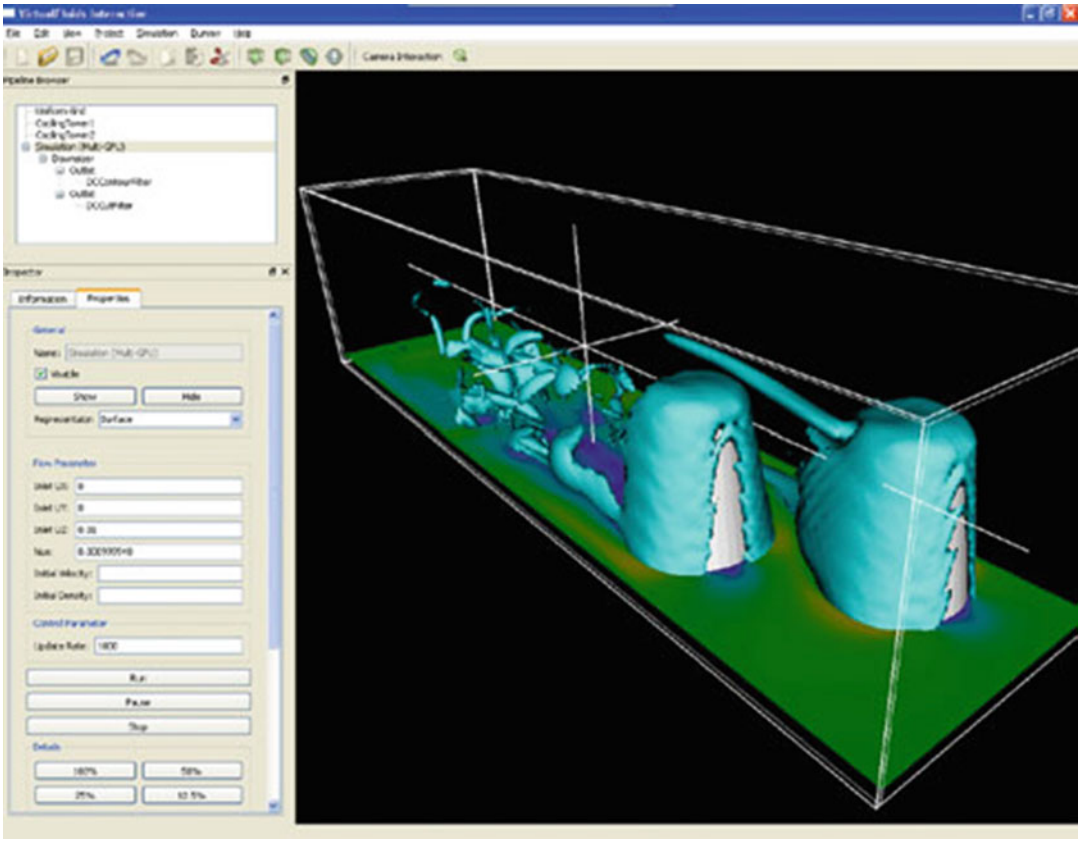
Challenges of Using Mobile Devices for High-Performance CFD

Mobile device hardware is designed to maintain a delicate balance between performance and power efficiency. In addition, mobile device software is designed to enable an uninterrupted user experience ensuring (UIs) remain available at all times. All applications written for mobile devices must necessarily be multi-threaded. The restriction on the number of parallel threads and the reduction in priority of threads other than the UI thread are compromises applied by the mobile operating system (OS) in order to maintain this balance.

Developer design guidelines, such as those provided by Google for Android application design, are an essential source of advice when writing native applications where delivering every last bit of performance possible is the primary aim. However, when developing for mobile devices, we must accept that the compute capacity is simply not on the same level as desktop systems. Researchers have recently explored the potential of using local clusters of mobile devices to share computing power through peer-to-peer networking (Harwood (2019)). Ultimately, Harwood and Revell (2018) conclude that the trade-off between accuracy, speed, and power consumption is explored with the choice of problem resolution ultimately being characterized by a desired accuracy, flow speed, and endurance of a given simulation.

GPU-Based Approaches

In addition to mobile devices that allow to run numerical simulations in the palm of your hand, another recent trend is to harness the parallel computational power of graphics processing units (GPUs) not only for rendering purposes but also for general-purpose applications. Effectively, the availability of these compact, highly efficient accelerator boards introduced a new era of local supercomputing. NVIDIA introduced the first GPU in 1999 (NVIDIA 2013a) as a dedicated rendering machine, handling all pipeline steps from vertex generation to pixel operations. Prior to the release of the GeForce 256, the vertices of objects were generated and processed on the central processing unit (CPU) and then sent to an add-in graphics accelerator like the 3dfx Voodoo card, which generated and processed primitives and fragments, and finally operated on the pixels (Kirk and Hwu 2010; Patterson and Hennessy 2011; Akenine-Moller et al. 2008). In late 2006 NVIDIA then released the GeForce 8800 (G80), one of the first unified graphics and computing GPUs (NVIDIA 2013a). Using the NVIDIA CUDA API and the built-in CUDA cores of the GeForce graphics card, programmers without any background in graphics or familiarity with the graphics pipeline were now able to implement their code on GPUs. This level of graphics card utilization for general-purpose applications is called GPGPU computing. Ever since the release of NVIDIA's G80, a continuous growth in compute capability regarding floating-point operations per second (FLOPS), memory bandwidth,

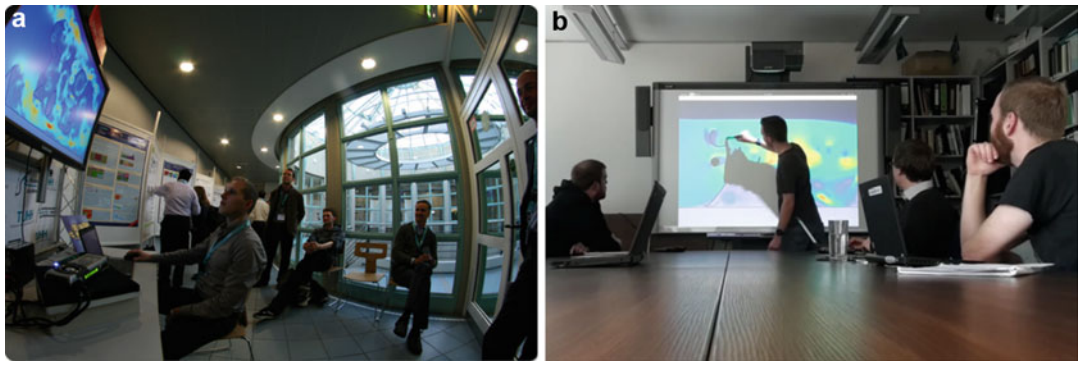


Computational Steering for Computational Fluid Dynamics, Fig. 6 The VirtualFluids Interactive simulation environment showing the airflow around cooling towers. (Taken from Linxweiler et al. 2011)

and number of transistors and streaming processors took place (NVIDIA 2013b). As an alternative to traditional massively parallel computing, GPU computing has also gained popularity in the CFD community as it allows for interactive 3D simulations at reasonable problem sizes, as discussed in the following.

Hybrid Visualization Approaches (GPU + CPU)

Linxweiler et al. (2007, 2011) adapted GPU computing for computational steering in CFD and demonstrated the benefits from the use of GPUs. They developed a single desktop application (VirtualFluids Interactive) (Fig. 6) integrating a complete pipeline for interactive CFD simulation including pre- and post-processing as well as the simulation. In this approach the preprocessing and visualization are running on the CPU; likewise, the simulation is executed on the GPU. The example shows that convergence of massive parallel computational power and a steering environment into a single system significantly improves the usability, the application quality, and the user-friendliness. Furthermore, using multiple GPUs, the approach allows for 3D simulations close to real time even for reasonable problem sizes. In this case, responsiveness significantly benefits from avoiding common bandwidth and latency bottlenecks inherent with traditional HPC clusters. Those can be avoided as GPU computing does not generally require network communication, which also reduces the complexity of the application. Compared to traditional massive parallel environments, GPUs are affordable for small to medium enterprises and do not require additional HPC knowledge from the end users. In addition, GPUs reduce power consumption with a much better performance-per-watt ratio.



Computational Steering for Computational Fluid Dynamics, Fig. 7 ELBE*vis* in action: (**a**) during the poster session at the GACM 2013 conference in Hamburg, Germany, (**b**) in a typical classroom situation on a smart board. (Taken from Koliha et al. 2015)

Direct CUDA-OpenGL Interoperability

While the previous approach benefits from a featured user interface with maximum usability, the method still relies on frequent data transfer from the GPU device back to the host and vice versa. Such extensive communication via the PCIe bus hinders real-time simulations and interactivity, as already discussed. For some applications, alternative concepts where visualization and data management happen completely on the device have shown to be more feasible, without moving or copying any data from or to the host during the simulation at all.

Delbosc et al. (2014) present an implementation of an optimized three-dimensional real-time thermal and turbulent fluid flow solver with a performance of half a billion lattice node updates per second. The method then has been applied to study the time evolution of the turbulent airflow and temperature inside a test chamber and in a simple model of a four-bed hospital room (Khan et al. 2015).

The authors of Koliha et al. (2015) present ELBE*vis*, a framework that is based on OpenGL-CUDA interoperability (NVIDIA 2013b) and maps OpenGL buffer objects, to the CUDA context for use in its respective memory space. This allows CUDA routines to read and write from and to data arrays that are then used for rendering. The OpenGL graphics API has been chosen by the authors to generate the images displayed on the screen due to its widespread use and platform independence. OpenGL wraps graphics driver calls into C commands and provides additional functionality for vertex, primitive, and fragment generation and processing. Libraries such as the OpenGL extension wrangler (GLEW) or the OpenGL utility library (GLU) were utilized to make use of OpenGL function bundles.

Due to the minimal-invasive concept and the high performance of the numerical solver, ELBE*vis* allows for very responsive interactions between the user and the numerical simulation. In Fig. 7, two examples for the use of ELBE*vis* are shown, for a 2D application case with simple inlet/outlet boundary conditions on the left/right end of the computational domain. The simulation is run on an NVIDIA GTX Titan board that is attached to an off-the-shelf laptop through an ExpressCard slot. The user can control the visualization by selecting the desired visualizer features, color maps, and so on. On top, the computational domain can be modified by freely drawing shapes. The effects on the flow field can immediately be observed, which makes the coupled solver a great tool for understanding the basics of fluid mechanics. Glessmer and Janßen (2017) discuss how to successfully use ELBE and ELBE*vis* in different teaching scenarios for Bachelor, Master, and PhD level work.

Apart from these interactive real-time applications, ELBE*vis* can also be used for simulations that run *near* real time, as the visualizer still

allows to control of the simulation progress and to analyze the flow field characteristics. For example, Überrück and Janßen (2017) elaborately discuss the simulation of wave impact. The highly resolved numerical simulations were run approximately one order of magnitude slower than real time and could benefit from the innovative visualizer concept. Thanks to the interactive monitoring of the simulations, without time-consuming file-I/O and subsequent visualization with CPU-based visualizer tools, information on the sloshing process and the model quality could be extracted easily as discussed in the entry.

Summary

Tremendous developments in recent years have brought more and more computing power to the desktop and into the end user's palm. Harnessing this power requires innovative concepts for the visualization of the numerical data and, at the same time, allows for innovative new concepts of computational steering. Successful examples include interactive steering in the context of conventional CPU solvers, solvers that make use of GPU acceleration and, most recently, first attempts to use the compute power of mobile devices for numerical simulations and computational steering.

Computer Games: Video Games
Artificial Intelligence: Machine Intelligence; Artificial Cognitive Intelligence

Definition

Computer Games are games that are realized in one form or another using digital hardware. Artificial Intelligence is commonly considered a branch of Computing Science which has matured to become a field of its own right. It is concerned with the creation/simulation of intelligent behaviour in/by machines.

Background

In the context of computer games and the computer games industry, games have become an essential part of the software and entertainment industry (Saarikoski and Suominen 2009). Recently there is increased interest in games (Lowood 2009) from a sociological, cultural, and educational point of view (Hildmann and Hildmann 2012a, b). For decades now, it has been argued that games and the playing of games are culturally significant (Mechling 1987).

Games and Game Theory

Games have traditionally existed in versions involving more than one player (Books 2010) and those that do constitute a formalized form of interaction that is more than physical activity or information exchange. The literature on games in general – as well as on specific games and their individual rules – is extensive (Tylor 1879). In the field of game theory, which is concerned with the formal analysis of games and their properties, one traditionally (Nash 2001; Osborne and Rubenstein 1994; von Neumann and Morgenstern 1974) distinguishes a variety of game types:

- *Noncooperative vs. cooperative games*: With regard to the actions available to a player during a game, we call an action *primitive* if it cannot be decomposed further into a series of other, smaller actions. The distinction is then made on the basis of whether such primitive actions are performed by individual players (*noncooperative*) or by groups of players (*cooperative*).
- *Strategic vs. extensive games*: A game is strategic if all decisions of all players are made a priori (i.e., before the start of the game) and independent of the opponent's decision (e.g., *Paper-Rock-Scissors*). Extensive games allow for decisions to be made during game play and with respect to the opponents moves (e.g., *Chess*).
- *Perfect information vs. imperfect information*: In, e.g., *Chess* both players have perfect insight into the state of the game; thus *Chess* is a game of perfect information. However, in most card games, there is an element of uncertainty as one normally does not know the distribution of cards for the opponents. The latter games are imperfect information games.

Today, games are mainly of interest to the AI community if they are too complex to calculate all possible variations. For example, the game *Nim*, though having a rich mathematical theory behind it, is small enough to calculate a winning strategy (Conway 2001). Due to its mathematical

foundation, it has left its mark on combinatorial game theory through terminology (e.g., *nim-addition* and *nimsum*) (Jørgensen 2009). However, it is possible to precalculate the moves and play a perfect game as there are known algorithms for doing so (Spencer 1975); thus the theoretical winner is already known, and there exist straightforward algorithms to determine which side will have this advantage (Bouton 1902). Due to this, the game is uninteresting today for both game theoreticians and researchers in AI. This was not always the case though, and in the early years, a number of devices were built to play the game: e.g., "Nimatron," built by Westinghouse for the New York Worlds Fair in 1940 (http://www.goodeveca.net/nimrod/nimatron.html) or "Nimrod," developed for the Festival of Britain in London in 1951. These games were the highlights where they were shown, with Nimatron playing 100.000 games (and winning 90.000) and Nimrod "taking on all comers" at the Festival in London (Jørgensen 2009).

Games and Artificial Intelligence

Yan (2003) lists artificial intelligence as an inherent design issue for online games, and indeed, "appropriately challenging" AI is considered to be crucial to the commercial success of a game (Aiollil and Palazzi 2009). Generally it can be said that "non-repetitive, adaptive, interesting, and in summary intelligent behavior offers a competitive edge for commercial games" (Naddaf 2010).

As the combinatorial challenge of complex games such as *Chess* and *Go* (discussed below) is successively mastered, some emphasis (e.g., Hildmann and Crowe 2011) is placed on designing AI players that instead of playing *very well* can play *realistically* in the context of playing non-repetitively and in an interesting way. Emphasis is placed on intelligent *behavior* (Hildmann 2013) in the way that a human player would play, including the handicaps, shortcomings and common mistakes made by humans (Hildmann 2011).

Besides the commercial interest of the gaming industry, the research field itself has always had a large interest in games. The prime example is the game of Chess – famously called the "Drosophila of AI" (McCarthy 1990). It was used by key figures in the field of artificial intelligence (such as, e.g., Claude Shannon 1950; Allen Newell et al. 1988; Herbert Simon 1970) in the context of their research on machine and human intelligence. The interest in this game predates the computer age: Charles Babbage already considered using his "Analytical engine" to play Chess in the 1840s, and by 1949 researchers on both sides of the Atlantic were advancing theoretical approaches to automate the playing of this game (Hsu et al. 1995). Similarly, *Checkers* was used by, e.g., Arthur Samuel to study learning (Jørgensen 2009).

In the past, specifically the Atari 2600 game console has been used extensively as a platform for developing and demonstrating AI algorithms. The reasons for this are the that there are over 900 game titles available for the Atari 2600 console, the games are simple and concentrate on the problematic aspects of the game (while newer games showcase the latest in video and graphic performances), they have a small and discrete action space, and many emulators are available (Naddaf 2010). Games will continue to be a focal point of AI research. For example, the game *Octi* (Schaeffer and van den Herik 2002) is a game specifically invented to be resistant to computer algorithms.

Ethical Considerations

Many things, including far-reaching business and political decisions, can be modeled as a game, and the application of artificial intelligence to the therefore broad area of games has stirred many controversies over the years. Among the relevant discussion topics are whether a computer can be said to *play* at all and whether computers should be *allowed* to play with (meddle in) some of the more serious matters that can be cast into a game-theoretic model.

For example, Weizenbaum (1972) and Wiener (1960) wrote on the moral and ethical issues of AI and allowing computers to make decisions, the latter being criticized by Samuel (1960) and the

former by Coles (1972). Taube (1960) wrote in response to Wiener (1960) that machines cannot *play* at all. He supposes that the act of *playing* is in line with *enjoyment*, and the author makes the distinction between the notions of *game* as it is "used in the usual sense" contrasted with *game* after it is "redefined by computer enthusiasts with nothing more serious to do."

Johnson and Kobler (1962) agree with Wiener (1960) that machines can be original but warn of allowing them to play war-games and simulations of nuclear war, as their predictions might not be entirely accurate and they would lack the understanding of all the values that need to be considered (i.e., to gain the insight ultimately exhibited by the fictional computer system "Joshua"). While the moral issues of artificial intelligence and political decisions have recently become a mainstream matter of discussion, this was already discussed in the context of game theory and its application to the nuclear "first strike" doctrine in the cold war. It was a well-known matter of disagreement between Wiener and vonNeumann; the latter advocated the idea of a preemptive nuclear strike on Russia. His argument was that their reasoning would lead them to the same conclusion, making it simply a matter of time before one side struck first. Since the mid-1990s, computers have successively dismantled the reign of human players in the realms of perfect information games. More recently, this has also happened in games with imperfect information, where intuition or the understanding of complex real-world relationships is required. Machines are increasingly mastering the decision-making in situations that go beyond those found in Chess and Go. Whether mastery of these situations includes the understanding that, e.g., "mutually ensured annihilation" is undesirable even if it constituted a victory *by points* is a question worth asking (but not the subject of this entry).

Landmark Artificial Intelligence Victories

Games are culturally important (Sutton-Smith 1986) and have been used for millennia to allow humans to exercise the brain (Smith 1956) and to compete against each other on the basis of mastery of skill and *intelligence*.

Therefore, games have been of large interest to the AI community, and the design of programs that can match the performance of human top players has been considered the ultimate achievement for a long time. Once a program can hold its own against a human, the next step is to try and outperform humans, and since the mid-1990s, one game after the other has been mastered by computers: in 1995 a program called "Chinook" played the game of Checkers at world class level and succeeded in beating one of the world's best players (Kroeker 2011). In 1996 "Deep Blue" beat the reigning world champion in the game of Chess for the first time in history (Kasparov 1996), and 1 year later, it won an entire chess tournament, ending the supremacy of humans in this game (Schaeffer and van den Herik 2002). The TV show game *Jeopardy!* was conquered decisively by "Watson" in 2011. *Poker*, a game of bluffing and intuition, was mastered in 2015 (Bowling et al. 2015) and within months from each other (December 2016 and January 2017), two programs, "Libratus" (Riley 2017) and "DeepStack" (Moravčík et al. 2017), significantly outperformed dozens of professional and top human players. Finally, the best human players of Go – the board game considered by many to be the last great stronghold of human superiority in games – recently succumbed to "AlphaGo."

Since 2005 the Stanford Logic Group of Stanford University, California is running the *General Game Playing Competition* (http://games.stanford.edu/) (GGPC) (Genesereth and Love 2005) which is inviting programs to compete in playing games. The games to be played are, however, unknown in advance, and the programs have to be able to compete in a number of different types of games, expressed in a Game Description Language (Love et al. 2008). "AlphaGo Zero" recently not only learned the games *Shogi*, *Chess*, and *Go* – all of which had defined computer programs for decades – from scratch (at a significant computational cost, Silver et al. (2017)), it also proceeded to beat the best programs currently available for each of these

games. This might be an indication that the GGPC competition might also soon come to an end. Progress is occurring at a nonlinear speed, and certainly in the area of artificial intelligence, the recent years have seen milestone events happen with increasing frequency.

Before we briefly elaborate on some of the most prominent examples of artificial intelligence systems winning against top human players, it should be pointed out that there does not seem to be a *silver bullet*, as the discussed games were conquered with different techniques and approaches. The game of Chess was essentially conquered by throwing sufficiently large amounts of computational resources at it (as well as training the program to play a specific human opponent) while the original program that mastered Go used advanced machine learning techniques (combined with *Monte Carlos Tree Search* (MCTS)) and had access to a large database of previously played games. Its revised version (which learned to play Go as well as Chess from scratch) relied on learning from massive numbers of games it would play against itself. In contrast, the program that won *Jeopardy!* applied probabilistic methods before selecting the most likely answer. A full technical discussion of these programs is beyond the scope of this entry; the interested reader is referred to the provided references for in-depth discussion on the matter.

Chess: Deep Blue

In his recent book (Kasparov and Greengard 2017), Gary Kasparov writes that over his career, starting at the age of 12, he played about 2400 *serious* games of Chess and lost only around 170 of these games. In 1989 he had played, and beaten, the computer program "Deep Thought." On February 10, 1996, playing as the reigning World Chess Champion, he lost a game of Chess to a computer, Deep Blue (Kasparov 1996), but still won the tournament. This date is significant for a number of reasons: firstly, and most widely known, for the first time (under normal tournament conditions), a computer program beat a top human player in a game which – until that day – was considered the ultimate benchmark for human versus machine intelligence (despite the game of Go being more complex). Far more importantly, however, is that Kasparov later claimed that during the game he "could feel" and "smell" a "new kind of intelligence across the table" (Kasparov 1996). What he meant was that the moves of his opponent bore witness to an intelligence that he, at the time, did not believe a computer could exhibit. It is not the superior play and triumphant victory at its end but the outstanding demonstration of insight and *intelligence* that makes *Game 1* of the 1996 "Deep Blue versus Garry Kasparov" match a turning point in the history of artificial intelligence. While Kasparov ended up winning the tournament (2–4), he had, arguably, conceded a win of the Turing test to Deep Blue. This test, famously proposed by Turing (1950), elegantly sidesteps the need to formally define the concept of *intelligence* before being able to assess it. It does so by suggesting that if the behavior of an opponent (as opposed to the physical appearance) could fool a human judge into believing that this opponent was human, then that opponent should be considered intelligent, independent of the embodiment of the intelligence. Arguably, in February of 1996, Deep Blue did just that.

In contrast, and despite being considered a "watershed for AI" (Hassabis 2017), when Deep Blue finally defeated Kasparov 1 year later in 1997 $\left(3\frac{1}{2} \text{ to } 2\frac{1}{2}\right)$, this constituted much less of a victory in the sense of the Turing test. This date is considered a "major success for artificial intelligence and a milestone in computing history" (Schaeffer and van den Herik 2002), but as Wiener wrote 37 years earlier, pure calculation is only a part of the process. One needs to consider the playing history of the opponent as well and be able to adapt to it accordingly during the game. In the case of Deep Blue, the machine knew every major game Kasparov had ever played while Kasparov was completely in the dark about Deep Blue's capabilities.

Of course one can argue that in 1996 this was true in reverse, as Kasparov (1996) himself acknowledged. He admitted that, after losing the first game, his defense "in the last five games was to avoid giving the computer any concrete goal

to calculate toward." He stated that he knew the machine's priorities and that he played accordingly; he closes by conjecturing that he has "a few years left." In fact, he had little more than a year before, on May 11th, 1997, Deep Blue won the deciding game of 6, thereby defeating the human world champion $3\frac{1}{2}$ to $2\frac{1}{2}$. The stronghold of human superiority and intelligence had finally fallen, and other landmark victories of AI were soon to follow.

Go: AlphaGo

Go has been described as the *Mount Everest of AI* (Lee et al. 2016b). This is fitting in the sense that it represents the highest peak we can climb but not necessarily the most difficult thing conceivable: Go is maybe the most complex game that is actually played by humans, with the number of theoretically possible games being in the order of 10^{700} (Wang et al. 2016) – a number expressing a quantity larger than the number of atoms in the universe (Lee et al. 2010). But if it was merely complexity we were after, harder challenges could easily be designed. However, it is also the fact that humans have engaged in playing Go for millennia and through this have reached high levels of mastery that makes it of interest to the AI community. In the context of squaring off humans against computers, Go is the likely candidate for the *ultimate* turn-based board game of perfect information.

From 1998 to 2016, competitions pitting computer programs against human players have been held every year at major IEEE conferences, with the handicap imposed on the human players dropping from 29 in 1998 to 0 in 2016 (Lee et al. 2016a). It is important to understand that the advantage gained from the handicap imposed on the human player is not linear in the size of the handicap. The handicap is implemented as stones the computer may place before the game starts; therefore, e.g., an advantage of 4 allows the computer to *claim* or *fortify* all four corners, while just one handicap (stone) less allows the human player to do the same for one corner, arguably allowing for entirely different game play (Lee et al. 2012), especially on a smaller (9×9) board. On a full (19×19) board, the step from a handicap of 4 to one of 3 was a massive one, and it was taken by AlphaGo in March 2016. Until then the reigning top computer program, "Zen" was only able to prevail against top professional players with a handicap of 4 (Lee et al. 2016b).

AlphaGo, created by DeepMind, entered the circuit around October 2015. It did not just capitalize on improved hardware and increased computational power; it was built differently and combined at least two successful techniques: Monte Carlo Tree Search (Cazenave 2017) with *Deep Learning* (DL) (LeCun et al. 2015). Technical details of DL are discussed in Clark and Storkey (2014), Gokmen et al. (2017), and Jiang et al. (2017). As the program played its top contemporary computer programs "Crazy Stone," "Zen," "Pachi," "Fuego," and "GnuGo," it proceeded to beat them all (winning 494 of 495 games with the single-machine version and triumphing in every single game with the distributed version) (Silver et al. 2016).

AlphaGo first beat the European champion Fan Hui 5 to 0 in September 2015 (becoming the first program ever to defeat a professional player) and within half a year proceeded to defeat the reigning human world champion Lee Sedol (who by some is "hailed as the greatest player of the past decade" (Hassabis 2017)) 4 to 1 in March 2016 (Fu 2016). It won the first three games, taking home a sweep victory (best of 5), but maybe more importantly it awed top human players, not unlike Deep Blue had awed Kasparov in 1996: commenting on the legendary move 37 in AlphaGo's second game against Lee Sedol, Fan Hui is quoted to have said: "[i]t's not a human move. I've never seen a human play this move, [. . .] So beautiful . . . beautiful" (Metz 2016).

Toward the end of 2017, AlphaGo Zero was introduced as the next incarnation of the system. It not only learned three games (Shogi, Chess, and Go) autonomously from scratch (Silver et al. 2017) but then proceeded to beat the top programs currently playing these games. In a way, AlphaGo Zero is not a program designed to play Go but a program designed to *play according to a set of rules*. More specifically, AlphaGo Zero can *at least* learn and play turn-based games of perfect

information without chance and has demonstrated its ability to play these games at the expert level.

As such, AlphaGo Zero might mark the end of this sub-area in computational challenges. We can (and will) surely continue to build better programs and let them play each other, but as far as the question of superior game play is concerned, humans have met (and created) their masters.

Poker: DeepStack and Libratus

Both Go and Chess are games of perfect information: all information about the game is known by both players at all times. *Zermelo's Theorem* (Zermelo 1913 – English version of the paper: Schwalbe and Walker 2001) states that deterministic (not based on chance) finite two-player games with perfect information [. . .] have a non-losing strategy for one player (i.e., either one player can, theoretically, force a win, or both players can force a draw). This means that – theoretically – one could calculate all possible versions the games of Chess and Go can be played and then simply never choose a move that results in a defeat. While this is practically impossible, due to the exceedingly high number of possible games, it means that for these two games – in theory – a machine could be built that would never lose a single match. Therefore it is only practical limitations that prevent computers from outperforming humans and all that it takes is clever algorithms that get around these limitations. That being said, actually achieving this has been considered a major achievement in the field (Jørgensen 2009) and by no means should the triumphs of Deep Blue and AlphaGo be belittled. As stated above, the defeating of the top human players in these games are landmarks in the history of artificial intelligence.

Heads-up no-limit Texas Hold'em, a popular version of the game Poker is considered the main benchmark challenge for AI in imperfect-information games (Brown and Sandholm 2017). In 2017, a Poker playing AI designed at Carnegie Mellon University (CMU), going by the name Libratus, prevailed against four top human players in a tournament and over the course of an aggregated 120.000 hands. Libratus became the first program to defeat top human players (Metz 2017). This victory has not come easy, as "Claudiro," an earlier program by the same team, failed in 2015. But while Claudiro was defeated, it was so only by a margin: after a combined $170 million had been bet, the humans were up by a mere 3/4 of a million (Tung 2015). Claudiro's performance, despite falling short of a decisive victory, indicated that Poker was not outside of what's possible. Within 2 years, its creators returned with Libratus, and another long-standing challenge in the field of artificial intelligence was met (Moravčík et al. 2017).

At the same time as Libratus was developed at the Carnegie Mellon University, another group at the University of Alberta designed DeepStack. By the time of Libratus' victory in early 2017, DeepStack had already competed in a tournament and won (in December 2016), with the resulting publication undergoing peer review. While DeepStack played 33 professional poker players from 17 countries, Libratus competed against four of the best human players in the world. Both programs showed a statistically significant superior performance over their human opponents (Riley 2017). DeepStack's performance exceeded the threshold of what professional players consider a seizable margin by a factor of 10 (Moravčík et al. 2017). Both programs approached the problem differently, which goes to show that the field of AI has not just chipped away at the (next) "last" stronghold of human AI, but it has done so in multiple ways, indicating that these victories were not achieved by machines capitalizing on human shortcomings but on progressively refining techniques which enable computers to improve their playing of the game.

Libratus is using a supercomputer at the Pittsburgh Supercomputing Center to build an extensive "game tree" to evaluate the expected outcome of a particular play. DeepStack instead uses a neural network to "guess" the outcome of a play, not entirely unlike how humans use "intuition" (Metz 2017).

Jeopardy!: Watson

In early 2011, a natural language question and answering program called Watson (named

after IBM's founder Thomas J. Watson (Brown 2013)) became world famous after winning the US TV show *Jeopardy!* (Kollia and Siolas 2016). This game show has been on TV since 1984 and revolves around contestants correctly identifying questions, on the basis of being given the resulting answers. The maximum time allowed is 5 seconds, and three contestants compete for being the first to correctly identify the question (Ferrucci 2010). Winning the game requires the ability to identify clues involving subtleties, irony, and riddles, and as such, the competition is firmly within areas where humans excel (and machines traditionally fail) (Brown 2013).

Over the course of 3 days, from February 14 to February 16, 2011, IBM's Watson proceeded to beat the two highest performing humans in the history of the game: Brad Rutter, who had been the show's largest money winner ever, and Ken Jennings, the record holder for the longest winning streak. Not only did Watson beat both humans, but also it utterly defeated them: in the end Watson had won in excess of $77,000 while its opponents combined won less than $46,000 (Ken Jennings $24,000 and Brad Rutter $21,600). The match was watched by close to 35 million people on TV and an estimated 70% of all Americans knew of the program (Baughman et al. 2014), making the program a bona fide celebrity.

Watson was the result of a 7-year project (Frenkel 2011), which resulted in a program that could interpret and parse statements made in often messy and colloquial English and search through up to 200 million pages of text to identify and generate the appropriate question (Strickland and Guy 2013) for the answers provided. For years to come, it was considered one of the leading intelligent systems in existence (Abrar and Arumugam 2013). IBM itself has claimed it to be the first software capable of cognitive computing (Holtel 2014) and considered its creation and victory at the game show the beginning of an "Era of Cognitive Computing" (Kelly and Hamm 2013).

The expert systems of the early years of artificial intelligence were systems that were designed to reason using learned (hard coded) steps. This process had to be painfully constructed on the basis of the testimony of human experts. In contrast, Watson uses probabilistic methods that result in *confidence* scores for answers (Ahmed et al. 2017). Due to this, the program is able to attempt answers to problems it has never seen before, i.e., it can operate under incomplete or missing information (Gantenbein 2014).

One more thing sets Watson apart from the computer programs mentioned before and their landmark victories: while being built to compete and win in the TV show *Jeopardy!*, the 3-day competition that made it famous was only a first step in its (intended) career. IBM considered the game show a real-world challenge in the area of *Open Domain Question Answering* (Ahmed et al. 2017), but winning against a human was a means to an end, not the goal. The ability to perform on human levels when subjected to open domain questions demonstrated for the first time that a program could engage in such an activity, independent of the setting or context. From the start Watson's creators had more in mind than merely winning a game show (Baker 2011). In what IBM has called *cognitive computing* (Kelly and Hamm 2013), the ability of programs to learn from experience and understand problems that were so far firmly in the domain of humans (Asakiewicz et al. 2017) has the potential to disrupt virtually all aspects of our lives, with all the commercial implications and opportunities that come with it.

The nonlinear increase in data generation, storage, and processing in recent years has arguably ushered in a new age, one where intelligent data analytics and text analysis (Cvetković et al. 2017) are rapidly increasing in relevance. The technology behind Watson has been applied to the domains of, e.g., legal services, health care, banking, and tourism (Gantenbein 2014; Murtaza et al. 2016). Of those, applications in the domain of health care constitute the largest benefit to society due to their societal importance (Kelly and Hamm 2013) and reliance on (massive amounts of) data (Ahmed et al. 2017). The exceptional performance exhibited during the game show, especially with regard to natural language processing and under the added challenge of colloquial speech,

ambiguity, and *reading between the lines*, has made it clear that the true calling for systems like Watson may be found outside the studio and in our daily lives (Kelly and Hamm 2013).

Philosophical Thoughts

Intelligence is a concept humans are very familiar with yet to date have failed to define well. Part of the reason why the Turing test is still relevant is because it sidesteps this dilemma by using the one definition human can agree on: human intelligence. If a human can be fooled to believe an opponent is human, then it must exhibit human-like behavior and, in this case, intelligence.

All games discussed above are landmark games in the area of artificial intelligence, but they are neither painting a complete picture nor are they the only ones that have been a key game for machines to compete against humans. One obvious example is the game of *Soccer*, where entire leagues of various machines compete for titles. In this entry, we entirely ignore the physical aspect of games and therefore all games that require physical behavior. The motivation for this is twofold: on one hand, the progress made in this area is equally stunning and pervasive, with new results and achievements being showcased in videos regularly. Providing a fair overview over these achievements is firmly outside the scope of this entry (the interested reader is invited to search for YouTube videos of, e.g., *Boston Dynamics*). On the other hand, this entry considers the term *intelligence* only in the intellectual sense and not in the context of mastery of the physical domain.

For millennia the mastery of certain games, often based on exceedingly simple rules, was seen as the pinnacle of human intelligence. Chess was considered an object of intellectual skill (Jørgensen 2009) and diversion (Spencer 1975). Professional Go players are known to describe promising board configurations as *esthetically pleasing*. In 200 BC, poetry and Go went hand in hand in Japan (Smith 1956). The complexity of games can extend far beyond what humans can consciously grasp and explain; many top players play games partly *intuitively*, that is, with a clear understanding of which moves they prefer but without the ability to justify this preference.

In the final years of the last millennia, this stronghold of human intelligence came under attack. While futile promises made by the most prominent experts in the field of artificial intelligence (e.g., Herbert Simon's "a computer [will] be the World Chess Champion before 1967" (Hsu et al. 1995)) have demonstrated time and time again that the advent of AI is not, by far, as sweeping and complete as they hoped, it seems inevitable and unstoppable.

In this context, it is important to remember that these are *just* games. These are controlled environments with often very clearly stated rules (Naddaf 2010). In addition and maybe far more importantly, these are interactions in which the evaluation of an outcome is clearly defined and often one-dimensional (i.e., win vs. loss). Real life is of a different complexity, and humans do not share the same views on how outcomes are evaluated. Artificial intelligence may be able to outperform humans in any one subject, but the true benchmark for intelligence may be a matter of defining the meaning of the concept *intelligence* for us. Machines are bound to be faster and more precise than humans; there should be no surprise about that. Whether they can be better at something than humans is really a question that cannot be answered until we know what *better* means, in the respective context.

One thing is becoming painfully obvious: we are running out of games to have computers beat us at. Maybe the age of game-playing AI is coming to an end. Or maybe the games need to change, and *winning by points* is no longer the victory we prize the most. Cooperative game play, with teams of humans and AI players working together, might be a new challenge in the years to come. In the end, when one has mastered a game to perfection and is guaranteed to never lose a match, *the only winning move is not to play.*

Definition

Computer games are all games that are played using a computer to display the board, generate events, and provide other players to play with or, generally, for any other game relevant aspect. The *entertainment industry* is a wide term to encompass any business generating profit from their activities related to the entertainment sector.

Introduction

The MITS Altair 8800, released in 1975, is often considered to be the first true personal computer (Wolf 2008). Its operating system was created by two guys from a young company (then still called "Micro-Soft") who offered it as a product to MITS before they had actually written it. These young men (Bill Gates and Paul Allen) soon went on to also sell IBM an operating system (MS-DOS, written in 8086 assembly) for their x86-based computers. While this does not mark the first time that hardware and software became two separate products, it is arguably the most famous one as the renamed company, *Microsoft*, went on to become a giant of the industry. While there are many fascinating aspects to the time and these companies, the fact that MS-DOS already used hidden and undocumented features to disrupt competitors' products (e.g., later MS software products would not work correctly unless the computer was running on MS-DOS – as opposed to their competitors' version of DOS – as its operating system) is the most relevant here.

Ever since then, the industry has kept changing its business models (Ojala and Tyrvainen 2011) and how to protect them. Computer games are a good product family to illustrate and discuss this. They are by many considered an essential part of the software and entertainment industry (Hildmann and Hildmann 2012), but one that is historically understudied (Saarikoski and Suominen 2009). There is no comprehensive analysis of the history of video and computer games from a business point of view (Royer

2011), yet. For a general account, we refer to, e.g., Purcaru et al. (2014) or Dillon (2016).

Computer Games Driving the Hardware Industry

Wolf (2008) and others say that it was the computer games that (financially) drove the evolution from computers the size of warehouses to the PC; from the 1975 MITS Altair 8800 to whatever model and type is considered state of the art at the time the reader is reading this. Whether computer games alone deserve the credit for this transformation, which is at the heart of the communication and information revolution of the last decades, is arguable; whether computer games have become (and been for 40 years now) a best-selling product is not a question at all. In the entertainment industry, they have long since replaced traditional board and card games in overall profit (Bohannon (2008) estimated gaming to be a $11 billion industry globally in 2008; in 2016 this is the economic impact of the gaming industry to the US GDP alone (Anderton 2017)) with the global industry exceeding $90 billion (https://tinyurl.com/ya7tfobf (venturebeat.com)).

The next paragraphs will sketch the century-long development from Charles Babbage's Analytical Engine early in the nineteenth century (Spencer 1975) to the video game culture of today (Kushner 2011; Williams 2017).

From the Arcade to the Living Room (The Rise of Atari)

This pervasive euphoria for computer games was not always the case. For example, the 1958 game *Tennis for Two* did not receive wide public attention or marketing (Nyitray 2011). Until 1972 commercial computer games came only in the form of arcade games, sold by companies like Midway, Bally, and Atari (Mazor and Salmon 2009). While Magnavox found itself selling its analog home TV game *Pong* in respectable numbers, they decided to shift their business paradigm from selling the consoles to selling the games (i.e., introducing different ROM cartridges that would all run on the same console). As far as home consoles are concerned, Ralph Baer's television-based *Brown Box* (1966–1967) and *Magnavox Odyssey*, released in 1972 (the year of *Pong*) (Montfort and Bogost 2009), are considered landmark hardware when it comes to lineage and impact on design (Nyitray 2011). Three years later, in 1975, Atari started building arcade games for the private use (Wolf 2008), i.e., home versions. These consoles included *Pong*, but as they were basically stand-alone units, built on a game-by-game basis, production took a long time and was very costly. In October 1977 Atari released the VCS (Video Computer System) 2600, which could be fed with cartridges of individual games. This product did well and ultimately became the most successful of the early game consoles (Royer 2011). However, financially speaking, it did not do well enough in its initial years. The 1978 arcade game *Space Invaders* (by Tomohiro Nishikado), which was licensed by Atari for the home market, partly rescued them from the losses of 1977–1978 (Montfort and Bogost 2009). Historical reviews such as Glenday (2009) rank the game as the top arcade game ever, and its arcade version famously caused coin shortages in some countries. The game's 1980 VCS release is considered to have multiplied Atari's console sales.

Digital Rights (The Fall of Atari)

What became Atari's final mistake was that they did not protect their developmental investment into the consoles. At the time a shift in the business model happened, in the sense that the profit did not come from the sales of the consoles themselves anymore but from the subsequent sale of individual games. Unfortunately (for Atari), the only protection against *some guys in a garage* starting to write their own games was the fact that Atari did not offer a programming manual or the console blueprints to just anyone.

According to (Levy 2010), Atari *"regarded the workings of its VCS machine as a secret guarded somewhat more closely than the formula for*

Coca-Cola." So when Activision was formed in 1980 (Royer 2011) by some of Atari's best coders gone rogue, it marked the eventual end of Atari's unprecedented success (and the console industry as a whole), simply because the soon increasing number of game-producing companies did not have to pay any royalties for the use of the consoles on which their games were being played. As O'Donnell (2009) states, *"[a]ny company capable of determining how the 2600 worked and willing to pay for the cost of producing cartridges could then market their games, which set a low bar for quality."* This raid on the profit of the console-producing companies (bearing the full financial burden and risk of providing the platform for the games) combined with the sudden flood of mediocre games (which both disappointed the consumer as well as caused the dumping of prices) let to the collapse of the industry in 1983 (Royer 2011). The age of Atari lasted a mere 6 years, but it turned a generation of kids into computer game players, computer (game) programmers (Aspray 2004) and, eventually, computer scientists. The credit for doing this does – of course – not go to Atari alone; the company is mentioned as one (admittedly very dominant and rather famous) example of what today is a global multibillion dollar industry.

Copyright Protection and IPR (From Nintendo to Today)

It took another 2 years and another company to bring about a change in the market. Nintendo's introduction of the Nintendo Entertainment System (NES) (A number of NES games are emulated and playable online at http://www.virtualnes.com) in the winter of 1985 became a turning point in the history of the industry (O'Donnell 2009) and even has implications for the Digital Millennium Copyright Act (DMCA) of 1998. The system required an *authorization chip*, the 10NES, to be present in the cartridge. Atari tried unsuccessfully to reverse engineer the chip and even went as far as to physically disassemble the chip (to no avail). The introduction of this chip is considered the moment when the industry changed from protecting its hardware to protecting copyright. Since the chip was required to be in the cartridge in order for the game to work in the console, preventing the chip from being copied meant to control the games that could legally be sold for a console. It is noteworthy that the design of the 10NES chip was integral to this, as the similar approach taken by SEGA failed. Accolade, who had reverse engineered the SEGA system to be able to circumvent it and publish games for the Genesis III, ended up winning a court case against SEGA (O'Donnell 2009).

There are a few differences between the protection mechanism for the NES (by Nintendo) and the approach taken by SEGA to protect their Genesis III:

1. Instead of a special chip such as the 10NES, SEGA relied on the string SEGA being found at a specific position in the memory of the game cartridge. Writing this string to correct location in memory required the knowledge of *what* to write *where* but did not require a specific (and protected) chip.
2. In addition, when the string was present on a game cartridge, SEGA had its game console display the text *"Produced by or under license from SEGA Enterprise LTD"* before starting the game. This, however, meant that anyone using the game including the string without permission (i.e., payment of royalties to SEGA) effectively infringed on SEGA's trademark.
3. Finally, as the string in memory was originally written by SEGA, copying it could be considered a breach of the copyright of SEGA's code.

While the initial ruling was in favor of SEGA, Accolade successfully appealed and subsequently won the case, with one of the arguments being that the string in memory was tiny in comparison to the amount of code written for the actual game and that the copyright breach was therefore negligible. In addition, the clever use of SEGA's trademark as a copy protection mechanism was ruled to constitute a violation of certain legal restrictions placed on the use of trademarks. Since then, the industry (computer games and the computer industry in general) has continuously changed to ensure the

protection of the companies' investment into intellectual property (mainly the software).

Summary and Conclusion

According to Ojala and Tyrvainen (2011) over the last decade, the software industry has taken the shape of a $200 billion software division within a $500 billion service industry. Even the latest offline digital rights management (DRM) tools, such as Denuvo (https://www.denuvo.com/), fail to adequately protect against piracy. One famous example of this is the case of *Resident Evil 7* in 2017 which was cracked within 5 days (https://tinyurl.com/yaaluusm (www.dsogaming.com)). Additionally offline DRM systems can have impacts on the performance of a game (http://www.sega.com/denuvo) and even block paying customers. This leads to two approaches by the industry: either a complete move away from DRM as done by CD Projekt Red's gaming platform *Good-Old-Games* (https://www.gog.com) or the move to a cloud-based DRM as done by Valve's platform Steam or others. Tommy Refenes (Super Meat Boy developer) states *"the fight against piracy equates to spending time and money combating a loss that cannot be quantified"* and *"[d]evelopers should focus on their paying customers and stop wasting time and money on non-paying customers."* While cloud-based online DRM systems made it harder to make illegal copies of software (and, as Ojala and Tyrvainen (2011) point out, specifically games), they can also lead to a loss of reputation and customers. While Steam managed to introduce a semi-online DRM (allowing for up to 4 weeks in offline mode) and still be considered a positive influence for PC gaming by providing additional services (https://tinyurl.com/ycp4c9be (www.cinemablend.com)), others have failed here. For instance, Ubisoft's original always-on DRM leads to some backlash from the customers especially when the servers for the DRM are not reachable (https://tinyurl.com/y97alctv (kotaku.com)). In this case it leads to a switch in the company policies removing the always-on demand for single-player games (https://tinyurl.com/yb8w795f (www.rockpapershotgun.com)).

Introduction

A computer game for people with disability may be for people with a sensory disability, motor disability, intellectual disability, learning disability, weak communication skills, weak social skills, or a combination of these. This chapter is a concise survey which includes representative games for each category of disability. Games addressing disorders that do not fall in any category of disability are not in the scope of this survey. The goal of the survey is to make the readers aware of the types of disability for which computer games have been developed. It does not include work at the intersection of games and disability which primarily falls in any of the following categories: (i) identifying design considerations or requirements using interviews, questionnaires, or data collected from gaming sessions without emphasis on specific games; (ii) platforms, architectures, or frameworks for creating games; (iii) interfaces or controllers for games; (iv) using hardware and software such that gamification is very limited, like use of stars to motivate the player; (v) game proposals, standards, or designs that are not implemented or evaluated; (vi) games which were either not evaluated or whose evaluation did not involve healthy subjects, subjects with a disability, or specialists; (vii) factors affecting acceptance of games; (viii) games for training members of educational or medical staff, such that these games are not designed to be played by people who need to be evaluated to see if they have a disability or disabled people who need to be treated; (ix) educational apps with very limited gamification; (x) challenges in design, development, or evaluation of games; (xi) automating or improving fulfillment of tasks in design, development, evaluation, customization, localization, or enhancement of games; (xii) reporting on digital-game-related resources or their strengths, weaknesses, or limitations; (xiii) use of disability-inspired games to serve areas other than disability; (xiv) comparison of digital games with other forms of education or entertainment; and (xv) digital games for helping people with a disability get familiar with assistive technology.

Games for People with Sensory Disability

Most computer games for visually impaired players give them feedback using audio, haptics, or enhanced imagery. Most computer games for hearing-impaired players give them feedback using a sign language. Moustakas and others (2011) report on a framework for real-time communication between visually impaired and hearing-impaired game players in a shared environment, along with experimental evaluation.

Their framework uses gesture recognition, sign-language analysis, sign-language synthesis, speech analysis and synthesis, and haptic interaction. Visual information about the gaming environment is conveyed to the visually impaired player via haptic interaction. Semantic information about the gaming environment is conveyed to the visually impaired player using sound. Verbal input from the visually impaired player is perceived using speech recognition. Sounds of musical instruments are used to enable the perception of colors using the SeeColor utility. Verbal information is presented to the hearing-impaired player using sign language. The hearing-impaired player can provide input to the system through the sign-language recognizer. The framework communicates the visually impaired player's input to the hearing-impaired player by recognizing the former player's speech and synthesizing signs for the speech for the latter player. The framework conveys the hearing-impaired player's input to the visually impaired player by recognizing the former player's signs and synthesizing speech for the signs for the latter player. When the visually impaired player touches a virtual object, he/she hears the sound synthesized for the object's color. Training is needed to help visually impaired players link colors with sounds. The visually impaired player and the hearing-impaired player play the game cooperatively, with the odd-numbered steps played by the visually impaired player and the even-numbered steps played by the hearing-impaired player. Translation between speech and signs occurs via text. Speech is translated into text and the text is used to generate signs. Signs are translated into text, and speech consistent with the text is generated.

Lanyi and others (2011) have reported on several serious games for people with learning disabilities and sensory impairments. A very small percentage of such people have jobs. *Cheese Factory* (Lanyi et al. 2011) is a game which teaches the concepts of fractions and percentages. *My Appearance* (Lanyi et al. 2011) is a game involving morning tasks that are typically completed after getting up and before leaving home. *3D Work Tour* (Lanyi et al. 2011) is a game which simulates the first days at a workplace. *VR Supermarket* (Lanyi et al. 2011) is a game which teaches shopping and money management during shopping using a shopping list, shopping cart, shelves with goods with their names, prices, and images, and a virtual wallet containing banknotes and coins. *Memobile* (Lanyi et al. 2011) is a game involving important tasks that are typically performed before leaving the house and throughout the day, e.g., packing lunch, taking money, and taking medications. *Stress at Work* (Lanyi et al. 2011) is a game which educates on stress at work. These games were evaluated by people from three countries who specialized in psychology, children with special needs, and IT administration.

Martinez and others (2019) report on SATReLO. It is a tool which allows construction of personalized mini-games for helping children with loss of hearing speak a language and write in a language. A therapist can select the language attributes (articles, pronouns, nouns, objectives, and verbs) to be included in the mini-game. The therapist can also select the theme of the mini-game. The theme can be animals, school supplies, or professions. *Domino* and *Sequence Cartoon* are the mini-games that SATReLO allows a therapist to customize. Some of the children used in the evaluation of SATReLO had a cochlear implant or a hearing aid. The rest had normal hearing.

A baby infected with Zika virus before birth may have a smaller head, joints with limited range of motion, seizures, and problems in vision and hearing (https://www.cdc.gov/zika/healtheffects/birth_defects.html). Filho and others (2020) report on a platform for evaluating executive functions of toddlers and training them. This study included 18 toddlers born with Down syndrome and 16 toddlers born with Zika virus. Let's Smile (Filho et al. 2020) is a game which shows sad white faces which become smiling colorful faces when touched. Let's Blow the Balloon (Filho et al. 2020) is a game which shows colored withered balloons tied to a string. The player is expected to keep the button below a balloon pressed, to fill the balloon with air. The balloon expands until it touches the top of the screen. When the balloon cannot be inflated anymore, the player is expected to move the finger away from the button that was

pressed for inflation, and touch the balloon to pop it. The assessment criteria for Let's Smile included proportion of hits without repetitions, and proportion of precision without error. The assessment criteria for Let's Blow the Balloon included holding time and reaction time.

Games for People with Motor Disability

Burke and others have reported on virtual-reality games and webcam games for post-stroke rehabilitation of upper limb (Burke et al. 2009). *Catch* (Burke et al. 2009) for bilateral rehabilitation requires the player to move a physical basket with magnetic sensors attached to it, to catch objects falling in the virtual environment which has a virtual basket. *Whack a mouse* (Burke et al. 2009) requires the player to move a hand with a sensor attached, to hit the mouse in the virtual world with a virtual hammer, in the first level of the game. Mouse and dog appear in the second level of this game, but the player should not hit the dog. This is for improving the player's visual discrimination and selective attention. *Rabbit Chase* – a webcam game (Burke et al. 2009)– is for rehabilitation of one arm. There is a rabbit which moves between four holes and the player must touch the hole with the rabbit when the rabbit stares from it. *Arrow Attack* (Burke et al. 2009) is a webcam game for rehabilitation of both arms. The player should touch the right arrow when the right arrow reaches the right box, using the right hand. The player should touch the left arrow when the left arrow reaches the left box, using the left hand. Burke and others (Burke et al. 2009) also report on a game which allows the player to play a *virtual vibraphone* – an instrument like xylophone, through remote controllers. This game is for rehabilitation of wrist and arm.

Hernandez and others (2014) present Liberi – a networked, cycling-based game – to help youth with motor disabilities socialize while being on special recumbent stationary bicycles. Players pedal to move their avatars. A player aims using a joystick and invokes game actions with one button. Liberi consists of six mini-games. Players are grouped fast since their avatars just have to stand on a launch pad and one player has to press action button on game controller to form their group. Voice links to other players are established immediately. Players can join a mini-game in progress by standing on its launch pad and pressing the action button. All avatars move at the same speed despite the differences in pedaling speeds. This avoids skill-based segregation of players. Some of the mini-games have goals only for group of players, and all players get the same reward when their group achieves its goal. Ten youths with cerebral palsy, including seven boys and three girls, played the mini-games from their homes over 10 weeks. On average, each player spent 2.75 h/week playing Liberi. All players spent the majority of the time playing with others when at least one other player was available. This showed that Liberi was successful in promoting group activities among the players.

E-Wobble (Karime et al. 2011) is an interactive rehabilitation system for stroke survivors who are unable to raise the foot at the ankle. The system includes a plastic wobble board, an accelerometer, vibration motors, a microcontroller, a wireless communication module, a sensorized sandal on top of the board, and a two-dimensional digital golf game with which the wobble board interacts. The sandal has cushioning in the area for the toes, with a pressure sensor placed below the cushion to detect the force exerted on it. The player has to move his/her ankle to move the golf ball. The player has to exert pressure on the cushion by flexing the toes, in order to drop the ball into the hole.

Zavala-Ibarra and Favela report on design and development of video games played with a custom-designed interaction device, to assist in detecting the early signs of dynapenia which is age-related loss of muscle strength and power (Zavala-Ibarra and Favela 2012). The interaction device contains Vernier Hand Dynamometer to measure the user's grip strength. One game requires the player to throw a ball. The player is given feedback about the amount of strength used by them. Another game allows the player to increase the altitude and the speed of the bird by pressing the controller. The third game asks the player to perform a maximum voluntary

contraction using the dynamometer and then maintain their force for as long as possible. The time elapsed between the start of application of the maximum force and the drop to half of the maximum force is the *muscle fatigue resistance*. The player is able to make the fire-extinguishing vehicle hold the water longer by retaining the force applied.

Dysgraphia is a nervous-system problem affecting fine-motor skills, causing handwriting to be consistently distorted or unclear (https://www.webmd.com/add-adhd/childhood-adhd/dysgraphia-facts). Kariyawasam and others (2019) report on a game-based screening-and-intervention tool for dysgraphia, dyslexia, and dyscalculia. Children in their study wrote Sinhalese letters on a mobile screen with a pen. Some of these children had *letter dysgraphia*. Children's writing was used as data for machine learning. A neural network and support vector machine (SVM) were used. Children predicted to have letter dysgraphia can be initially trained to write letters correctly by showing them animations to help in following the given paths. Children are allowed to write independently in later stages of intervention. Children were asked to write the 10 integers ranging from 0 to 9, for getting data for using machine learning for diagnosing *numeric dysgraphia*. The authors used a Random Forest classifier to predict if a child had numeric dysgraphia or not. Children predicted to have numeric dysgraphia can use animations to help in tracing the given numbers.

Games for People with Intellectual Disability, Weak Communication, or Weak Social Skills

Isasi and others report on a game about healthy eating which is playable on an iPad (Isasi et al. 2013). The game is intended for 8- to 12-year-old children with Down syndrome. The game consists of two mini-games. The first mini-game requires the player to iteratively select ingredients to make a salad. The player is shown two ingredients on each iteration, such that only one of them is suitable for salad. The second mini-game requires the player to choose foods to create a well-balanced breakfast.

Wyeth and others (2014) report on Stomp-a floor-based system requiring simple gross-motor actions. Stomp is designed for people with intellectual disability. Players interact with the digital worlds by triggering the pressure sensors embedded within a floor mat. There are interactive experiences that are projected onto the mat. Stomp can be used by one or more people, by stepping, stomping, pressing, jumping, or sliding. Players stomp on icons to make their selection. The experiences provided by Stomp included three musical experiences, three sports experiences, a painting experience, a paddling experience, a road-safety game, a sheep-herding game, and four arcade-like experiences. Players can interact with Stomp while sitting, standing, walking, or lying down. They get visual and auditory feedback. Stomp promotes physical and social activity. People with cerebral palsy, communication disorders, mental retardation, autism, or Down syndrome, used Stomp.

Hassan and others report on a game to teach usage of money to 9- to 14-year-old autistic children (Hassan et al. 2011). The game teaches children to recognize banknotes and choose correct banknotes for purchases. The game also includes communication with the shopkeeper to teach social skills to children.

Games for People with Learning Disability

There are differences between intellectual disability and learning disability. A person with an intellectual disability faces challenges in more than one area. These areas include communication, completion of activities of daily living, learning, speaking, memorizing, foreseeing, and physical movement. A person with a learning disability may face challenges in one or more areas of learning. Dyslexia is a learning disorder that affects the ability to read, spell, write, and speak. (https://www.webmd.com/children/understanding-dyslexia-basics). Dyscalculia is a brain-related condition which makes basic arithmetic hard to

learn (https://www.webmd.com/add-adhd/childhood-adhd/dyscalculia-facts). Kariyawasam and others (2019) used a Convolutional Neural Network, KNN (K-Nearest Neighbors algorithm), and audio clips of children's pronunciations of words and letters to predict if children were dyslexic. They report on a multisensory gaming environment to offer intervention for children predicted to be dyslexic. The hard stage requires the child to pronounce the displayed word. If the child pronounces the displayed word correctly, the balloon bursts, and the child is congratulated by the gaming environment. These authors used the gaming environment to let children show their ability to count numbers, compare numbers, and add numbers. The authors used counting accuracy, time spent per counting question, number-comparison accuracy, time spent per number-comparison question, addition accuracy, time spent per addition question, and an SVM (Support Vector Machine) classifier, to predict if a child was affected by dyscalculia or not. The gaming environment is used to offer intervention to children predicted to have dyscalculia.

Visual memory is the ability to immediately recall what the symbols, shapes, objects, or forms just seen by eye looked like. Visual memory is important for processing short-term memory into long-term memory (https://www.optometrists.org/vision-therapy/guide-vision-and-learning-difficulties/guide-to-visual-information-processing/visual-memory/). A person can have poor visual memory despite normal vision and hearing. Pir and others (2019) report on Neuroland which is an application containing 10 digital mini-games for improving visual memory. Each of these games except two shows letters, words, shapes, or ships, and expects the player to select an option containing all of what was just shown, containing none of what was just shown, containing a color not present in what was just shown, containing a suitable subset of what was just shown, has color of what was just shown, or is of shape identical to the shape that was just shown. Words Chain displays some words for a few seconds, removes them from the screen, and expects the child to say them in the order in which they were displayed. Fish Aquarium displays aquariums with one fish in each. All fish differ in size. The child is expected to remember the size and location of each fish. Then fish are removed and aquariums without fish are displayed. The child is expected to select the aquariums sequentially such that each aquarium selected earlier had a fish that was smaller than the fish in every aquarium selected later. The study reported in (Pir et al. 2019) involved 24 8-year-old girls and 24 8-year-old boys. Of these, 12 girls and 12 boys were included in the experimental group and the remaining 24 children were put in the control group. The experimental group received intervention using Neuroland. The control group did not receive any intervention. The results showed that these mini-games were significantly effective in enhancing visual memory and writing skills.

Games to Promote Awareness of Disability

Gerling and others (2014) report on four mini-games that the player needs to successfully play to arrive at the party. These games are played by a person in a real wheelchair such that movements of the wheelchair control movements of the digital character. These mini-games are designed to make people not using wheelchairs aware of the challenges faced by users of wheelchairs and promote empathy toward them. One mini-game requires the avatar to cross the street while being in a wheelchair when the avatar arrives at an intersection. Another mini-game requires the avatar to find the items on the shown list while avoiding puddles inside a grocery store, and move the arm to reach the items. Another mini-game requires the avatar to pick items from a bookstore with multiple floors, using elevators instead of escalators. The arm needs to be used to grab items. Cake, cream, and candles are examples of items to be picked from the grocery store. Birthday cards and wrapping paper are examples of items to be picked from the bookstore. *Park* – one of the mini-games – requires the avatar to come to a park and get three flowers. The avatar must avoid stairs. After completing the four mini-games, the player navigates the streets to arrive at the friend's

house for the birthday party. Twenty-one females and 19 males participated in this study.

Game-based learning (GBL)

Introduction

Computers have been used to create and play games for basically as long as they are around; according to Nyitray (2011), the first publicly accessible computer games appeared as early as 1958, though the term *game* might be rather grande for some of the early games. The game *Pong*, considered by many as *the first*, famously consisted of the moving of a bar on one side of the screen to deflect a moving dot (i.e., a ball) back to the other side of the screen, where another player attempted to do the same. There is evidence that traditional board games such as *Checkers* were

developed (Jackson (2000) and *Tic-Tac-Toe* was implemented (Egenfeldt-Nielsen et al. 2008) as early as 1951. One of the motivation for using the then new computing paradigm for such a mundane thing as playing a game was to *"convey the message that our scientific endeavors have relevance for society"* (Nyitray 2011).

While many maintain that games do not seem to serve any cultural or social function other than to distract (Bogost 2007), we argue in this entry that there is evidence to the contrary. There is little doubt that games can be beneficial, if used correctly and by trained exerts. In fact, there is a vibrant and fast growing community of researchers and practitioners in the field of games-based learning (de Freitas 2011). That being said, it is important to consider the evidence from established fields such as psychology and pedagogics to ensure that the dangers and shortcomings of the games-based learning industry – which today is a billion dollar industry – are not to be overlooked. As it is to be expected for a relatively young field which promises many business opportunities, there are many projects that seem to take short cuts. Of course the use of computer games alone is not the end to all problems in pedagogics; professionals and researchers in the field have emphasized (e.g., Hildmann 2010) that computer technology, while showing a lot of potential and offering many benefits, is merely a tool for a teacher.

This entry provides the relevant background on long established fields such as pedagogics and developmental psychology. The aim is to inform the those interested in designing, implementing or using computer games for educational purposes and to highlight the potential benefits of doing so. However, the main message is that such games are a supporting technology, and not the dominant factor or even the core aspect to teaching endeavors.

Computer-Games Based Learning

Rowland and Gardner (1971) date the use of computers (and in a way, computer games) for educational purposes back to 1956 (Ricciardi et al. 1957). In this context, we will use the definition offered by Connolly and Stansfield (2007), who have suggested that computer (games)-based learning should be seen as *"the use of a computer (games) based approach to deliver, support, and enhance teaching, learning, assessment, and evaluation"*. When used appropriately, this means combining.

Validated approaches from pedagogics, known models from psychology and learning theory as well as adhering to best practices for the design and implementation of computer games and intelligent user interfaces.

If this is done correctly computer games have the potential to constitute a platform through which the experts can deliver their teaching in a way that makes use of all the befits while mitigating a number of normal human traits (such as e.g., waning attention and lack of motivation).

But the use of games for non-recreational purposes (i.e., as *serious games*) is certainly not new (consider that every maneuver is, in a way, a game and the literature on military maneuvers is more than 2000 years old, e.g., Tzu and Cleary 1988), nor is it restricted to education (Puschel et al. 2010): *business games* have been proposed for research as early as the 1960s (Babb et al. 1966) and 1970s (Rowland and Gardner 1971). Games have been used to great success to train complex problem management (Pasin and Giroux 2011) problem solving abilities (Christoph 2006) as well as practical and reasoning skills (Pee 2011). When used appropriately they can significantly reduce training time and demands on the instructor (Sandberg et al. 2001; Hildmann and Hildmann 2012a, b). In fact, (computer) games have been analyzed from a variety of perspectives, both negative (e.g., aggression, violence or gender stereotyping) and positive (e.g., skills development, engagement or motivation) (Connolly et al. 2008).

Games-Based Learning (GBL)

There are many positive aspects of the use of games for teaching in the literature. Arguably, games have never been *just* a children's medium

(Bogost 2007) and are generally something in which people of all ages engage in (Warren et al. 2011). Games have been shown to inherently drive high motivation levels in those that play them (Malone and Lepper 1987). Repetition is a core element to many games, which can be used to embody otherwise boring rehearsal tasks and e.g., large firms and companies have used game-like settings for decades to implement training session for employee training activities. The literature lists many areas where games have successfully been used as training and simulation tools: military training (Schneider et al. 2005), teaching exact sciences, specifically mathematics (Habgood 2007; Squire et al. 2004; Young and Upitis 1999), training in software engineering and computer science (Ford and Minsker 2003; Zhu et al. 2007) as well as medicine (Beale et al. 2007; Lennon 2006; Roubidoux 2005). Other fields where GBL has been applied are language education and project- and knowledge management (Johnson and Wu 2008; Rankin et al. 2006; Long 2010) and Christoph (2006); Chua (2005), respectively).

This indicates that for members of a society to engage in playful activity has the potential to significantly influence the later performance of individuals as well as entire groups. Every military maneuver (Giles 1974; Leonhard 1994) or every play-acting of, e.g., household situations – as often performed by children – can be seen as a game with educational content.

When investigating the aspects that are credited with making a gaming experience *fun*, many parallels are found with what researchers such as Gee (2003) and Tiotuico et al. (2008) think makes for a good learning experience. This is consistent with insights from psychology which have long since accepted that the playing of games is an important factor in the early development of children and young adults. Bruce (2004) showed that the act of playing during childhood can strongly impact social behavior later in life. Green et al. (2010) report on research that indicates that playing action video games can have a beneficial impact in decision making.

As far back as the 1970s, games have also been considered in the context of serving as a platform for research projects, e.g., Cohen and Rhenman (1961) or Rowland and Gardner (1971) and Babb et al. (1966) report on investigations on using management games or business games (respectively) for research. In recent years a number of conferences and academic circles have focused on this subject and the field is rapidly growing. Today, the teaching and learning paradigm is no longer restricted to human-human interactions: advanced research is now considering knowledge transfer between humans and machines (from the former to the latter) and e.g., Arsenio (2004) reports on using simple games to assist humans when teaching robots.

Key Concepts of (Computer) Games-Based Learning

The behavioral activity of engaging in *play* is considered by e.g., Brown (1998) to be a fundamental basis for development in complex animals, on par with the act of sleeping and dreaming. As mentioned above, it is considered a significant help for the process of maturing from children to fully rounded adults and a strongly determining factor in the shaping of a functioning member of society (Bruce 2004). Specifically, video games are said to have a unique persuasive power and to have the potential to support existing social and cultural positions (Bogost 2007). They can maintain high motivation levels and seem to center around a number of fundamental principles (Malone and Lepper 1987). We briefly discuss intrinsic motivation attributed to games and identify a number of key skills and abilities that are especially prone to be supported through educational games.

Intrinsic Motivation

Malone and Lepper (1987) offer a detailed argument on just how important intrinsic motivation is to the designer of educational (computer) games. They identify four individual factors as well as three interpersonal factors that are elementary to providing and maintaining intrinsic motivation (Table 1).

As stated by Connolly et al. (2008), it is safe to say that the effect of (computer) games-based learning has been analyzed from a variety of both negative (e.g., aggression, violence or gender stereotyping) as well as positive (e.g., skills development, engagement, learning or motivation) perspectives. In all these, as two successive comparative studies by Connolly et al. (2007a, b) have shown, *curiosity*, *challenge* and *cooperation* consistently emerged as the most important motivations for playing computer games.

Fundamental Principles of Good Games

Besides aiming at important aspects of intrinsic motivation identified in the previous section the game should aim to include as many as possible of the fundamental principles of good games. There is an extensive body of literature that tries to identify those principles; Gee (2003, 2004, 2005) identified the following (Table 2).

These principles are:

- *Identity*: Through fictional identities, a game stimulates the player to embrace a new role and to take on the corresponding responsibilities. Adapting this new role requires learning new domain knowledge.
- *Interaction*: Players experience responses/feedback to their actions.
- *Customization*: Customizing a game to the specific interests of a group elicits the group's interest and provide stimulating challenges.
- *Production*: Decisions of the players directly impact events in the game.
- Risk Taking: Since the game provides a standalone environment in a virtual world, actions in the game rarely have consequences in the real world, inviting the player to experiment and to take risks.
- *Challenge and Consolidation*: Through repetition, the player can master skills and advance through increasingly challenging stages.
- *Pleasantly frustrating*: Good computer games have realistically attainable goals that are, while achievable, at the outer edge of the players *regime of competence*.
- *Well-ordered problems*: Offering an underlying structure to presented challenges motivates the player to consider the problems on an abstract level. This allows to draw on previous experiences to solve future problems.
- *System thinking*: Good games encourage or even require players to think about the effect their decisions have on the course of the game. As a result a player considers abstract relationships instead of isolated events.
- *Agency*: Giving the player a sense of ownership over their decisions.

When creating a serious game, the designer should try to include and address as many of the above as possible. In the next section we discuss key skills that have been shown to be supported by GBL. It is unlikely that any one game will target all of these skills equally or even at the same time. The principles listed above should be adopted, but which principles should receive the largest attention will be determined by the targeted skills.

Key Skills Supported by Games-Based Learning

A (non-exhaustive) list of key skills that have been shown to be promoted by serious games has been published by Hildmann and Hirsch

Computer Games in Education, Table 1 The individual and interpersonal factors considered to be the main factors provide and maintain intrinsic motivation (Malone and Lepper 1987)

Individual factors	Interpersonal factors
Challenge	Cooperation
Fantasy	Competition
Curiosity	Recognition
Control	

Computer Games in Education, Table 2 Fundamental principles of good games, cf. Gee (2003, 2004, 2005)

Identity	Challenge & Consolidation
Interaction	Pleasantly frustrating
Customization	Well-ordered problems
Production	System thinking
Risk taking	Agency

(2008). For a detailed discourse on these the reader is referred to Healy (2006) (Table 3).

Considerations, Shortcomings, and Disadvantages

Computer games are more and more considered as tools in the education sector (Pee 2011). This interest notwithstanding, there are many negative aspects of games acknowledged in the literature such as e.g., the increase of aggressive behavior (Uhlmann and Swanson 2004) or the decrease in physical exercise (Liliana Escobar-Chaves et al. 2010).

Among these negative aspects is also the proven fact that computer games can be extremely addictive (which should be unsurprising since gambling, known to be highly addictive, is often embodied by a game). The fact that games can become an alternate reality to which the player can escape from real world problems has been widely discussed, and while this surely has large potential for negative consequences, it is also a property that motivates the use of games as educational tools: problems that real life scenarios and approaches inherently face can often be completely ignored in games.

Lack of Supporting Evidence

While we have motivated the benefits of using computer games in the educational sector, the GBL approach is far from being accepted by all practitioners in the field. There are plenty of reasons to caution against hailing the use of computer games as a silver bullet for all educational challenges. For example, an investigation conducted 25 years ago by Randel et al. (1992) found that only ≈50% of the considered studies showed any significant difference between using games and using conventional instructions. The field has certainly evolved since the 1990's and market analysts consider games-based learning to be one of the fastest growing division in the eLearning market (cf. Connolly et al. 2008), but commercial success does *not* imply the validity of an approach. As Gura (2005) cautions: *"[e]ducation is a highly politicized field, [. . .] littered with obstacles to reform and populated by powerful individuals with their own pet theories"*. The fact that there is a market for the idea does not imply that the idea works; it merely suggests that it is selling well. It is not uncommon that the performances and benefits claimed by the marketing departments of major game producers are met with considerable skepticism by some experts in the field (cf. Fuyuno 2007).

There is a shortage of solid evidence for the validity of using computer games for teaching, training and instruction Connolly et al. (2007b). Furthermore, a fair number of known shortcomings are in need of receiving more attention from the community. Examples of such open challenges are the distinct lack of frameworks or guidelines. GBL continues to attract attention by funding bodies and, to a lesser degree, acceptance as a mainstream approach for learning and teaching, and the focus should be on guidelines and frameworks to support other advances in the field.

However, it is also the case that games *for play* are often perceived differently from games *for serious purposes*. When this distinction is made by the player it can have a significant impact on the willingness to engage in a game and – as a result – on the benefits gained from playing that game. If knowing whether a game is meant to be serving a serious purpose affects the performance of the game, then cunning game design and the framing of learning activities becomes a significant factor. This makes objective evaluation even more difficult and once again highlights the importance of applying best practices from the fields of psychology and pedagogics when engaging in the development of serious games.

Computer Games in Education, Table 3 A summary of the key skills that can be promoted through serious games (cf. Hildmann and Hirsch 2008), for a full discussion the reader is referred to Healy (2006)

Problem solving	Communication
Analytical thinking	Discovery
Team working	Negotiating
Social and cultural	Logical thinking
Critical thinking	Visualization

Lack of Interdisciplinary Communication

The field of games-based learning and serious games is commonly dominated by experts from the computer games industry and commercially driven by companies. In Hildmann and Hildmann (2009), the authors emphasize the gap between approaches to teaching and learning offered through GBL and established models for human learning (from cognitive or behavioral psychology) or validated practices used by teachers in classrooms. In light of the large amount of funding recently offered for the development of new learning approaches, there is the danger of overlooking basic needs and requirements. This problem is well documented in the literature: Powell (2003) states that *"some education experts argue that the scientists who are now developing an interest in the subject are ignoring prior research"*, while Gura (2005) goes so far as to claim that *"[u]ntil now, science and educational research have not mixed well"*. While more recent publications increasingly acknowledge the need to integrate alternative approaches instead of imposing them on the field (e.g., McGonigal (2012): *"The future will belong to those who can understand, design and play games"*), there is still the issue of verification and comparison of the usefulness of contributions. While the short-term gains from heeding the advice of pedagogues, psychologists and practitioners in the training sector may be reduced, the long-term benefit (both financially as well as with regard to the actual performance of the created products) can only increase. Therefore, computer scientists and game designers have to start listening more to the practitioners. At the same time, the education sector is undergoing fundamental changes and teachers in a classroom have to accept that old teaching paradigms might have become outdated or may be falling behind what is technically possible. Even without challenging any of the established theories about how children learn, the world in which today's children grow up is vastly different from the world into which senior educationalists were born. All sides need to acknowledge that there are contributions from other fields, and that only by working together and fostering interdisciplinary communication can GBL achieve its full potential.

Definition

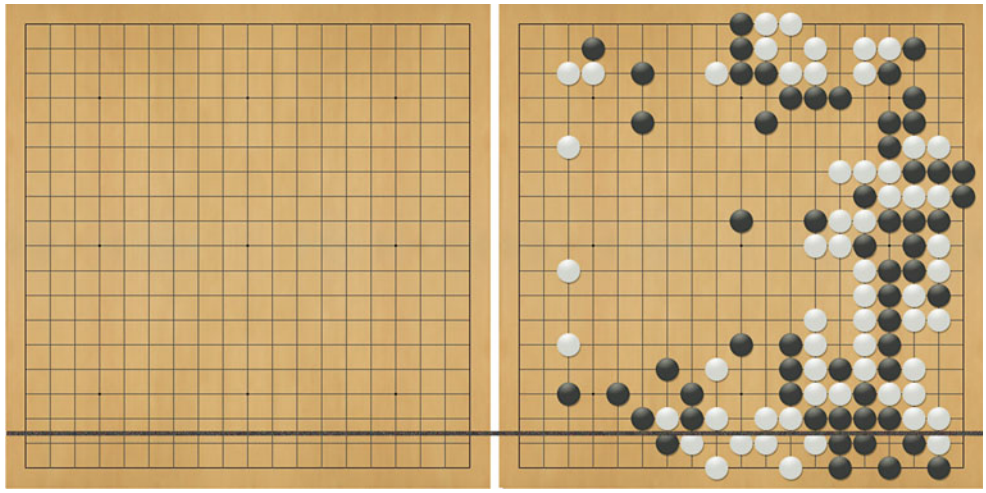
Computer Go was an interesting target in AI domain because Go was exceptionally difficult for computers among popular two-player zero-sum games.

Overview

As widely known, computers are now superior to human beings in most of the popular two-player zero-sum perfect information games including checkers, chess, shogi, and *Go*. The minimax search-based approach is known to be effective for most games in this category. Since Go is also one of such games, intuitively minimax search should also work for Go. However, despite the simple rules which had changed only slightly in these 2,000 years, Go is arguably the last two-player zero-sum game in which human beings are still superior to computers.

The solution to the difficulty of Go was a combination of random sampling and search. The resulting algorithm, Monte Carlo tree search (MCTS), was not only a major breakthrough for computer Go but also an important invention for many other domains related to AI. The strength of computer Go had rapidly improved since the invention of MCTS.

This entry consists of introduction to the game of Go and computer Go topics before and after the invention of MCTS.

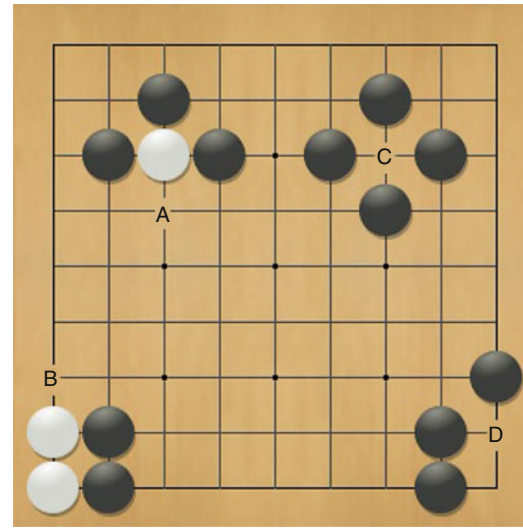


Computer Go, Fig. 1 *Left*, An empty 19*19 board. *Right*, middle game position taken from one of the most famous games in Go history

Game of Go

History of the Game

The game of Go originated in China and had been played for more than 2,000 years. It is one of the most popular two-player board games. The game is called *Go* or *Igo* in Japan, *Baduk* in Korea, and *Weiqi* in China. Because the Japanese Go association took main part in spreading Go to the world, *Go* became the most popular word for the game. The word *Go* will be used for this entry. Most of the players reside in East Asia but in the last century it got more popular in the rest of the world. The population of Go players is thought to be approximately 40 million. There are professional organizations in East Asian countries, and several hundreds of professional players belong to these organizations.



Computer Go, Fig. 2 Capturing and illegal move

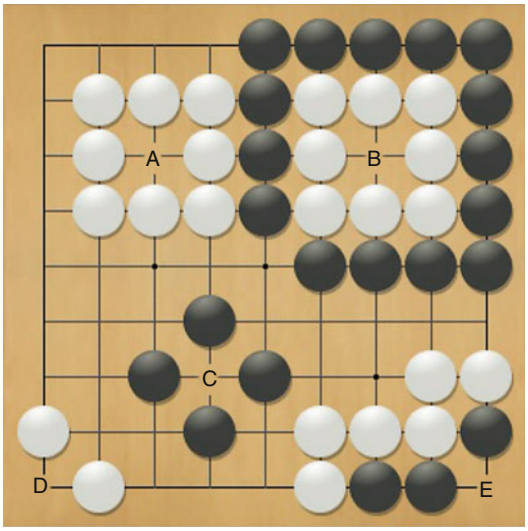
Rules of Go

Equipment

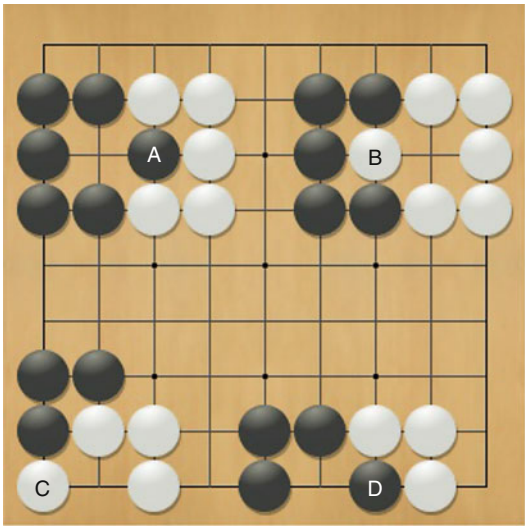
Go is played on a board with a grid. Players alternately place one stone at a time on an empty intersection of the grid. The first player uses black stones and the second player uses white stones. The aim of the game is to occupy as much *territory* as possible. A 19 × 19 grid is used in official rules. For beginners and short-time games, 9 × 9 or 13 × 13 grids are also used (the rule is independent of the size of the grid and it can be played on arbitrary-sized board) (See Figs. 1 and 2).

Capturing

Once placed, stones never move on the board. Stones get connected in four directions, vertically or horizontally (do not connect diagonally).



Computer Go, Fig. 3 Suicide moves, eyes



Computer Go, Fig. 4 Examples of Ko

Connected stones form a *block*, and if a block gets completely surrounded by opponent's stones, the block will be *captured* and removed from the board. Capturing opponent stones is often advantageous because it results in greater chances to occupy more territory.

Empty intersections adjacent to a block are called *liberties*. If a block has only one remaining liberty, the block is in *atari*. Capturing occurs if an opponent stone occupies the last remaining liberty of a block. Examples of capturing are shown in Fig. 2. If black plays on A or B, the white blocks are captured and removed, as shown on the right side.

Suicide and Eye

It is prohibited to place a stone if the stone (or the block which contains the newly placed stone) has no liberties. In other words, suicidal move is prohibited. For example, white is not allowed to play at C in Fig. 2.

However, black is allowed to play at B in Fig. 3 because it can capture the surrounding white block and make liberties for the black stone at B. In Fig. 3, A, D, and E are all illegal moves for black. B and C are illegal moves for white.

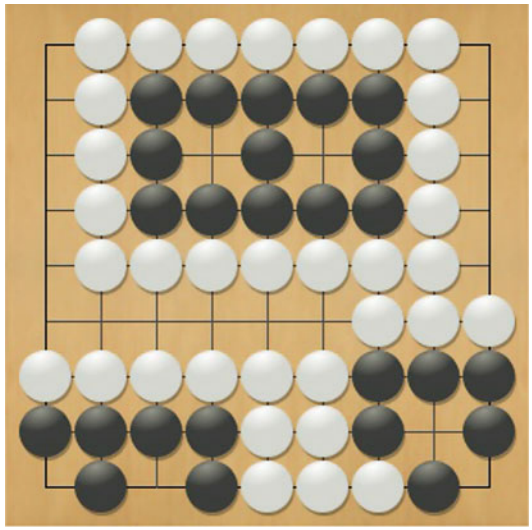
A single empty intersection surrounded by the stones of the same color is called an *eye* (in Fig. 3, A and D are white's eyes and C is a black's eye). Making eyes is important for the game (cf. section "Life and Death").

There is a variation of rules which allows suicide of more than one stones (e.g., New Zealand rules). It gives some effects to theoretical analysis but will not be described in details in this entry because it is rarely used.

Ko and Repetition

Similar to other board games, Go has a rule about avoiding repetitions. The simplest and most popular case of repetition occurs by capturing an opponent stone resulting in a stone with only one liberty. The example is shown in Fig. 4. Black captures a white stone by playing on A and then white can capture back the black stone by playing on B. The stones marked C and D are also in Ko. To avoid infinite recapturing, a player must play another move, called *Ko threat*, before capturing back. Ko adds more complexity in the game (both in practice and theory) and often makes it more interesting.

There are several variations in repetition avoiding rules. Super Ko rule prohibits global repetition (which of course includes simple Ko) (*Super Ko* means the global repetition.) For human beings, accurate detection of Super Ko during real games is difficult, and it is excluded



Computer Go, Fig. 5 Safe (living) blocks

from some of the official rules for human tournament (e.g., Japanese Go association official rules).

However, computer Go tournaments typically use Super Ko rule because it is not a problem for computers. There are two types of Super Ko rule. Situational Super Ko distinguishes the same board position if the next player is different and positional Super Ko does not.

Life and Death

If a player owns a group of stones (consisting of one or more blocks) which has two or more *eyes*, the group will never be captured by the opponent, unless the owner intentionally fills one of his own eyes (filling own eye is almost always a terrible move).

Groups safe from capturing are *alive*. If a group cannot avoid capturing, it is *dead*. As the game ends, all stones on the board will be either *alive* or *dead*. The black blocks in Fig. 5 are all alive. Life and death is not a part of the rule, but it is a natural consequence of the rules and the concept is crucial for the game.

End of Game and Scoring

For the game of Go, pass is always a legal move. Players can pass if there is no other beneficial move remaining. The game ends if two consecutive passes are played. If the game had ended by passes, the winner is decided by the score. (Of course, players are allowed to resign at any moment. The opponent will be the winner.)

There are two rules for scoring, *area scoring* and *territory scoring*. Area scoring counts the sum of:

- The number of empty points only one player's stones surround
- The number of stones of each player
- *Komi* points to compensate the advantage of the first player

Territory scoring counts the sum of:

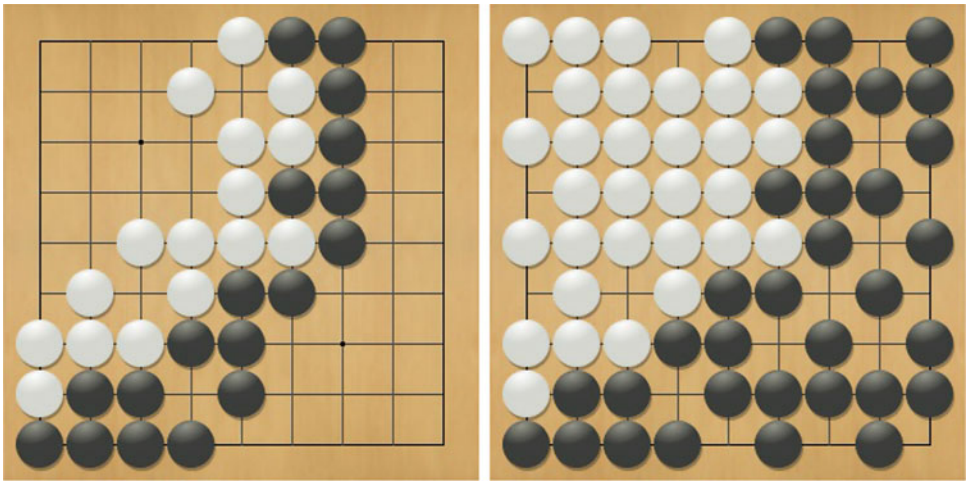
- The number of empty points only one player's stones surround
- Minus the number of stones captured by the opponent
- *Komi* points to compensate the advantage of the first player

The outcome is similar for both rules and the difference rarely affects human players. However, how to correctly handle territory scoring is an interesting topic for computer Go. Area scoring is more computer friendly and used in most compute Go tournament.

Strength of Human Players

Strength of the players is measured by *kyu* and *dan*. Human players are given a 25-kyu rank after learning rules. As players improve their strength, the number decreases until it reaches 1 kyu. Players of different ranks can play even games using handicap stones because having more stones in the opening is more advantageous. The difference between the ranks is used as the number of handicap stones (e.g., a 5-kyu player and a 1-kyu player play with four handicap stones).

Shodan (which means first dan) is given to players who are 1-stone stronger than 1 kyu, and then the number increases for stronger players. It normally requires more than 1 year of training to



Computer Go, Fig. 6 9 × 9 board endgame examples

Computer Go, Table 1 Computer strength for two-player zero-sum games without Monte-Carlo Tree Search (as of 2015)

Game	Strength
Checkers	Perfect play is possible
Othello	Stronger than human champion
Chess	Stronger than human champion
Shogi	Approximately as strong as human champion
Go 9 × 9	Approximately 3 kyu (based on authors' guess)
Go 19 × 19	Approximately 3 kyu

reach shodan. The strongest amateur players are rated approximately 9 dan. Professional players also use the same word *dan*, but the difference is not measured by the number of handicap stones (Fig. 6).

Computer Go Difficulty

Theoretically, minimax search can find the optimal move for two-player zero-sum perfect information games. For most popular games in this category, minimax search combined with alpha-beta pruning (e.g., alpha-beta search) actually succeeded in making programs which is at least as strong as human champion (Fig. 1). Go is the only exception in this category of games (Table 1).

Computer Go, Table 2 Search space size of two-player games

Game	Search space
Checkers	10^{20}
Othello	10^{28}
Chess	10^{45}
Shogi	10^{70}
Go (19 × 19)	10^{172}
Go (9 × 9)	10^{38}

Difficulty: Search Space Size

One of the difficulties of the game of Go is the enormous search space size. The search spaces of popular two-player zero-sum games are listed in Table 2 (numbers are from Schaeffer et al. 2014). The game of Go has the greatest search space size. Checkers was solved by exhaustive search in 2007. Go search space is far beyond the limit of current (and at least near future) computational power.

It is empirically known that computers tend to be stronger for smaller games if the rules are similar. However, there was a small difference in the strength of 9 × 9 Go and 19 × 19 Go for non-MCTS programs. This fact indicates that the search space size is not the only reason for the difficulty of Go.

Difficulty: Evaluation Function

Among the games shown in Table 2, only checkers is solved by exhaustively searching the game states. For the rest of the games, the search space is too enormous. Therefore, minimax search prunes unpromising branches based on evaluation functions. Fast and accurate evaluation functions for the games were made using a combination of handcrafted codes and machine learning techniques.

Despite the simple rules, Go was the only exception. It is widely believed that making evaluation function for Go is difficult compared to other two-player games. There are many explanations for the difficulty. Unlike chess, there is no clue such as the value of the pieces because all stones are identical. Unlike Othello, focusing on important portions of the board (e.g., corner points or edges) didn't work. Because it is a territory-enclosing game, it seems like it is possible to predict the final territory, but it is only possible in the late endgames. Seeking for local goals such as capturing opponent stones often does not help in finding globally good moves.

The best evaluation functions developed for Go (as of 2014) was either too slow or inaccurate. Minimax search does not work without an evaluation function. A survey paper published in 2002 (Müller Jan. 2002) listed research challenges in computer Go. The first challenge in the list seems very trivial: "Develop a Go program that can automatically take advantage of greater processing power." It emphasizes the fact that Go needed a new approach.

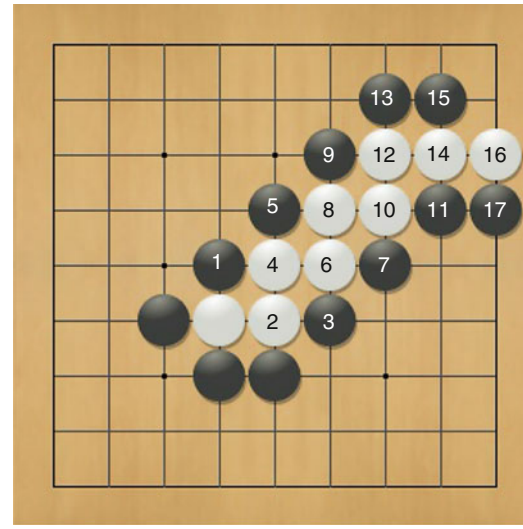
Before Monte Carlo Tree Search

Local Tactical Problems

The Go board is large enough to have multiple local tactical fights. Although there is no guarantee that locally good moves are globally good moves, blunders in local fights are often fatal.

Ladders

Ladder is a simple but important technique in Go. Capturing a block after a sequence of *ataris* is called a ladder, which normally results in a zigzag shape (Fig. 7). Many Go programs use ladder search as one of the tactical components.



Computer Go, Fig. 7 Ladder example

Semeai

Another tactical problem is the *capturing race or semeai*, which is a variation of capturing problems. Capturing race occurs when two groups of different colors are adjacent in an encircled space and can live only by capturing the other group. Normal algorithms for solving two-player games such as minimax search (alpha-beta search) and proof number search could be used to solve the problem.

Life and Death (Tsumego)

One of the most important local tactical fights is the *life-and-death* problems, also called *Tsumego*. (In formal definition, Tsumego means life-and-death problems with only one correct move, but it is often used as the same meaning.)

Killing (and capturing) a large group of stones is advantageous in general. Therefore, in real games, it is crucial to correctly analyze life and death of stones. Alpha-beta search-based solver and df-pn (depth-first proof number) search-based solver are both known to be effective.

If the problem is enclosed in a small region, these solvers are much faster than human players. However, open-boundary Tsumego is still difficult for computers.

Theoretical and Practical Analysis

Solving Go on Small Boards

The smallest size of the board which makes the Go interesting for human players is probably 5×5. Go on 5×5, 5×6, and 4×7 is solved by search (van der Werf 2015).

Computational Complexity

Go using Japanese rules is proved to be EXPTIME-complete (Robson et al. 1983). The proofs with Chinese rules, the class is only proved to be somewhere between PSPACE-hard and EXPSPACE.

Endgame Theory

Since Go is a territory-occupying game, the value of each move can be described as the amount of territory it will occupy. Combinatorial game theory (CGT) (Berlekamp and Wolfe 1994) shows how to systematically analyze the values of moves as a sequence of numerical values and how to choose the optimal move after these analyses. CGT solves difficult artificial positions better than human professionals, but there is no program which actually uses it in the play.

One-Ply Monte Carlo Go

Because it was difficult to make good evaluation function for Go, there was a different approach called one-ply Monte Carlo Go. (It was originally called Monte Carlo Go, but to distinguish from Monte Carlo tree search, the term one-ply Monte Carlo Go will be used throughout this entry.)

Because the number of legal moves decreases, it is possible for randomized players to end the game naturally according to the rules. If both players randomly choose one of the legal moves, the game will continue for a long time because filling own eyes results in repeatedly capturing large blocks. However, given a simple rule to avoid filling its own eyes, the game will end in a reasonably short time (average number of moves will be approximately the same as the number of the intersections of the board). In this way it is possible to evaluate the given positions by letting random players play both sides and count the territory. The random play sequences until the endgame is called *playout*.

The basic idea is illustrated in Fig. 8. A given board position will be evaluated by the average score of the playouts performed from the position. In the figure, black had won 2 out of 3 playouts. Therefore, the position might be promising for black.

This is an extremely simple idea. All legal moves are evaluated by playouts, and the move with the highest winning rate will be chosen (the left most branch in Fig. 9). Unsurprisingly, one-ply Monte Carlo Go is weak because of a fundamental weakness.

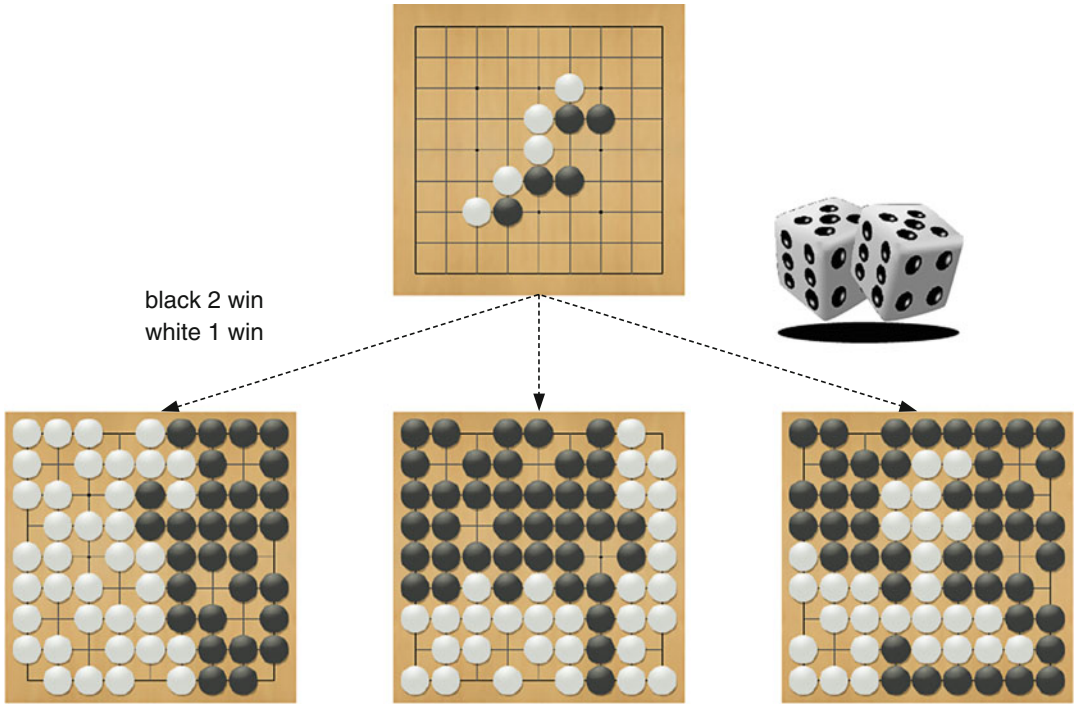
Assume that the playout is purely random except avoiding eye-filling moves. If there is a threatening move with only one correct reply, the opponent will likely to choose the wrong reply in the playouts. Therefore, such a move will be evaluated highly. The one-ply Monte Carlo Go program likes to play direct atari moves which are, in most cases, useless moves. In short, it tends to choose moves which expect opponents to make blunders.

The chance of choosing nonoptimal moves will not be zero even given infinite computational time. The limit of the strength is analyzed when using simple playouts. The winning rate against GNU Go on 9×9 board was approximately 10 %, and it was also extremely weak on 19×19 boards.

The first known work was described in an unpublished report written by Brügmann in 1993 (Brügmann 1993). There was more sophisticated approach based on one-ply Monte Carlo Go. They had comparable strengths with other approaches, but it was clearly not the most successful approach for Go. However this idea is important because it triggered the invention of the Monte Carlo tree search algorithm.

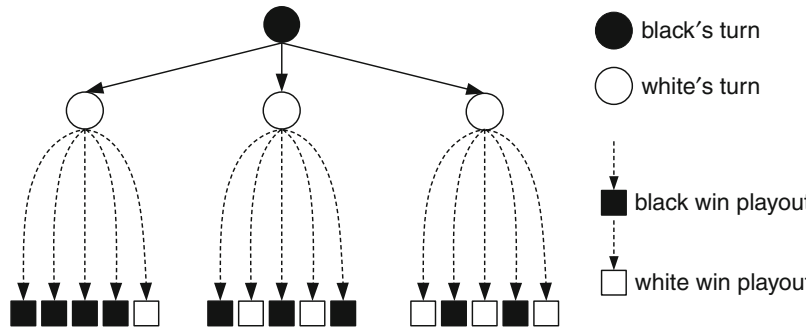
Monte Carlo Tree Search and Go Programs

As described above, one-ply Monte Carlo Go introduced a new way of evaluating the board position which does not require an evaluation



Computer Go, Fig. 8 A 9 × 9 board evaluation by playout

Computer Go, Fig. 9 Simplest one-ply Monte Carlo Go



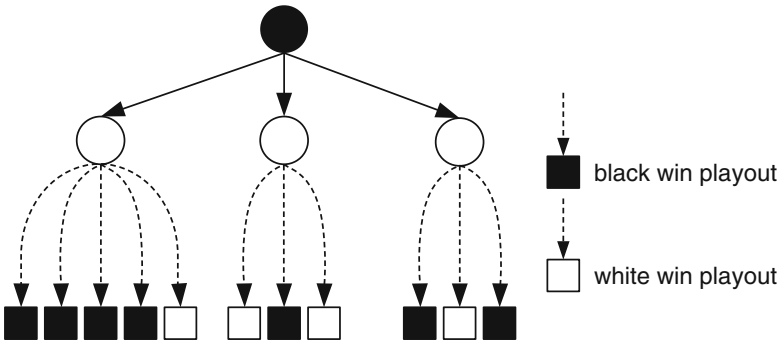
function. But there was also a fundamental weakness. The breakthrough came in the year 2006.

Brief History of MCTS Invention

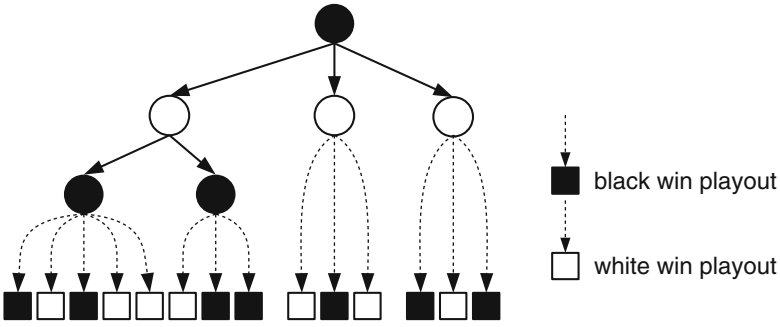
Go program Crazy Stone, developed by a French researcher Rémi Coulom, is the winner of the 9 × 9 Go division of the 11th Computer Olympiad taken place at Turin in 2006. The algorithm used in Crazy Stone was published at the same time in Computers and Games Conference which was one of the joint events with the Olympiad (Coulom et al. 2006). It is widely regarded that the algorithm developed for Crazy Stone by Coulom is the first MCTS algorithm.

Based on the success of Crazy Stone, Kocsis and Csaba Szepesvári submitted the paper about Upper Confidence applied to Trees (UCT) algorithm to ECML 2006 Conference (Kocsis and Szepesvári 2006). UCT had the proof of convergence to the optimal solution which Crazy Stone's first approach did not have (explained in section "UCT Algorithm").

Computer Go,
Fig. 10 Enough playouts on promising branches



Computer Go,
Fig. 11 Expand promising nodes



At first, it seemed MCTS works only for small boards. However, soon after the UCT paper was published, a Go program named MoGo became the first Go program to achieve a shodan on 19 × 19 board (Gelly et al. 2006) (on an Internet Go server, KGS (KGS Go Server 2015)) and became famous among Go players.

Basic Framework of MCTS

The differences between one-ply Monte Carlo Go and MCTS seem simple. First, more playouts will be performed from more promising branches (Fig. 10). Then if the number of playouts on a leaf node exceeds a threshold, the leaf will be expanded (Fig. 11). With these modifications, the tree will grow in an unbalanced manner growing toward the promising parts of the tree. It covers the weakness of the one-ply Monte Carlo Go programs and significantly improved the strength.

However, at this point, the definition of promising branch is not clear. The key point of the algorithm is the selection of promising branches which is explained in the following sections.

Theoretical Background: Multi-armed Bandit

The basic approach was surprisingly simple. However, promising branch has to be decided appropriately. Possibly the simplest approach is to select the branch with the highest mean reward. But it is obviously a bad idea, because if the first playout of the (unknown) optimal branch had lost, it will never be selected again. Therefore, the selection method has to give an advantage to branches with small number playouts. More formerly saying, for MCTS to be successful, branches with large confidence interval must be given a positive bias. Theories of the multi-armed bandit (MAB) problem gave a solution. MAB is an old problem which is studied from 1930s.

The problem settings are as follows. You have a certain number of coins and there is a slot machine which has a number of arms. Each arm returns a reward based on an unknown distribution. The goal is to find a strategy which minimizes the expected value of cumulative *regret*. Cumulative regret of a strategy is the difference between the sum of the expected reward of the strategy and the sum of the ideal optimal reward which could be obtained by pulling the optimal arm every time. (There are many different formulations of MAB but this entry focuses on the settings which is related to MCTS and Go.)

Intuitively, part of the coins must be used to explore the arm, and the majority of the coins should be spent on the optimal arm. This is called the exploration-exploitation dilemma.

Analysis of the theoretically optimal solution is already given in 1985 by Lai and Robbins (Lai and Robbins 1985), but their algorithm was complex and time consuming. Auer et al. proposed a tractable and also optimal (with constant factor difference) strategy based on upper confidence bound (UCB) (Auer et al. 2002). They proposed several strategies but here we only introduce UCB1. Algorithm UCB1 chooses the arm with the highest UCB1 value which is defined as

$$\mathrm{UCB1} = \overline{X}_i + C\sqrt{\frac{\ln t}{s_i}} \qquad (1)$$

where $\overline{X}_i$ is the mean reward of i-th arm, s_i is the number of coins spent for the i-th machine, t is the total number of coins spent so far, and C is a constant called the *exploration constant* which is defined based on the range of the reward. For the proof described in Auer et al. (2002) to hold, C should be $\sqrt{2}$ if the range of the reward is [0, 1]. However, it is also proposed that C should be adjusted for the target problems to achieve better performance.

The first term is the *mean term* and second term is the *bias term*. While arms with higher mean tend to be chosen, the bias term gives an advantage to arms with small number of coins.

MAB	—	One-ply MC Go
arm	—	move
coin	—	playout
nu. coins	—	thinking time
minimize regret	?	optimal move

Computer Go, Fig. 12 Relation between MAB and one-ply Monte Carlo Go

There is a close relation with MAB and one-ply Monte Carlo Go (Fig. 12). Each arm is a move, one coin is one playout, and the number of coins stands for the amount of the thinking time. The goal is slightly different, but as explained in the next section, UCB1 works well if combined with tree search.

UCT Algorithm

UCT is a tree search algorithm which uses UCB1 for branch selection. UCT does the following procedure repeatedly until a given time limit is reached or a given number of playouts are performed:

1. Follow the branch with the highest UCB1 value until reaching the leaf node.
2. If the number of playouts at the leaf exceeds a given threshold, expand the node.
3. Do one playout.
4. Update the values of the nodes on the path.

UCT is a generic algorithm which works for various problems, and it also has a proof of converging to the optimal solution if the range of the playout reward is in [0, 1]. However, in the same way, as the constant in UCB1, *exploration constant C* should be adjusted for UCT also (e.g., to make Go programs stronger).

Reward Definition and Playing Style

Crazy Stone attracted the attention of Go programmers not only with the strength but also with the unique playing style. It won many games by the smallest possible margin by intentionally (it looked like so) playing safe-win moves.

Play aggressively when losing; play safely when winning. It was a very difficult task for minimax search-based programs. But MCTS-based Go programs naturally acquire this ability. It is based on the definition of playout rewards. Since Go is a score-based game, it is possible to use the score itself as the reward. However, if the reward is two valued (e.g., 1 for win and 0 for loss), MCTS tries to maximize the winning probability, not the score difference. The early version of Crazy Stone was using the score as the reward, and the winning rate against GNU Go was in 30–40 % range. After the reward was changed to 0, 1, it jumped up to higher than 60 %.

Why MCTS Works for Go (Or Weakness of MCTS)

MCTS has a generic framework and it drastically improved Go program strength. But, of course, it is not an all mighty algorithm. Theoretical and practical analysis revealed the weakness of MCTS if the tree has a *deceptive structure* or *trap*.

A *trap* is a tree where a small number of branches have significantly better (or worse) values than other branches. If a long sequence *trap* is in the tree, it is highly unlikely for MCTS to find the correct solution. In Go the situation typically occurs in a *ladder* where only one move is the correct move and all others are blunders. Early MCTS-based Go programs did actually miss long ladders in real games.

A Go proverb says, "if you don't know ladders, don't play Go." It is impossible to make a strong Go program without correctly recognizing ladders. Recent Go programs handle ladders by playouts. As explained later in section "Playout Enhancements," playouts used in recent Go programs are far from random. The ladder sequences in real games are simple and playouts can solve them. From the viewpoint of the tree search algorithm, the *trap* is removed by playouts.

MCTS is a combination of tree search and playout. Playout can read simple deep sequences. Tree search can select the best branch from various options. If the combination is effective, MCTS works well. However, there are often needs for reading long sequences of moves in tactical situations (capturing or life and death is typical). It is difficult to make playouts correctly read tactical sequence. This is widely regarded as the remaining weakness of MCTS-based Go programs.

C

Enhancements for MCTS-Based Go Programs

RAVE and AMAF

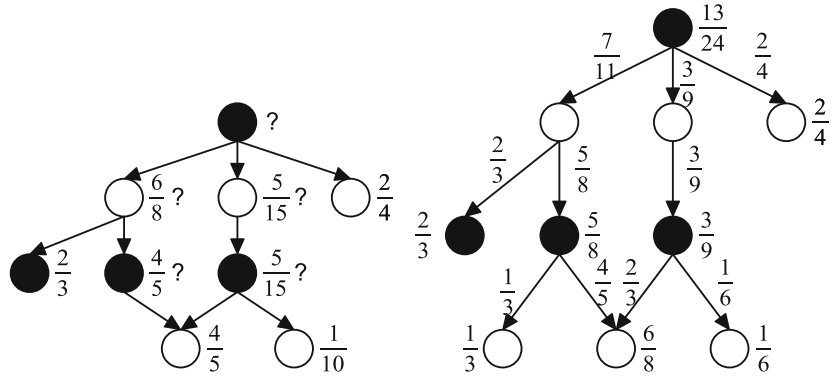
UCT has a proof of convergence and works fairly well, but state-of-the art Go programs (as of 2015) are not relying on UCT. Practitioners ignored the theory and replaced the bias term with other terms using Go knowledge. Rapid Action Value Estimation (RAVE) is one of the most popular techniques used in Go (Gelly et al. 2007).

Occupying a point is often crucial in Go regardless of the order of moves. A heuristic technique called All Moves As First (AMAF) heuristic is invented based on this observation. Instead of forgetting the sequence in playouts, AMAF updates the values of all moves that appeared in playout sequences. It is inaccurate but the update speed is improved by a large margin. In RAVE, branches with small number of playouts use AMAF-based values, and as the playouts increases, it is gradually replaced by true values of playouts.

Playout Enhancements

Improving playout quality is the most important and subtle part of MCTS-based Go programs. Both handcrafted approach and machine learning approach succeed (as of 2014).

MoGo had used handcrafted playouts, and it is said that program Zen (one of the strongest programs in 2014) also uses at least partly handcrafted approach. Many other programs use different approach. Pattern-based features are defined by programmers and the weights are adjusted by machine learning. Typically, game records played by strong players are used as training data, and the objective function will be the



Computer Go, Fig. 13 Transpositions and UCT

matching rate with the expert moves. In both approaches, the playouts will choose more "reasonable" moves which makes it possible to solve simple tactical situations including ladders. How to make good playout is still not clear because playout and tree search are correlated in a complex manner and theoretical analysis is difficult.

Progressive Widening

To find good moves in game playing, search must focus on promising part of the tree. In MCTS, *progressive widening* method is popularly used for pruning unpromising part. If the number of playout at a node is small, only few branches will be selected as the target of search. As the number of playouts increases, more branches are added.

Parallelization

Using shared memory parallel, MCTS is common for strong Go programs. Normal implementation based on lock mechanism achieves speedup on multi-core machines. It is also known that the performance could be improved by using *lockless hash* technique.

For distributed memory environment, root parallel approach is used by several strong programs. Each compute node independently searches with different random seeds, and a small part of the tree is shared among the compute nodes (e.g., tree nodes with depth 1–3 are shared). It is known to scale well for up to several dozens of computers.

Transpositions and MCTS

Game tree of Go is actually not tree but a directed cyclic graph. *Transpositions* often occur when different sequence of moves results in the same board position. As shown in the left of Fig. 13, it is not trivial to decide the win rate of nodes for DAGs. Efficient handling of transpositions in MCTS is still an interesting open problem (Fig. 13).

Go programs uses mainly two ways. One is to ignore transpositions and use trees. This is wasting computational time, but it is possible to make strong enough programs based on trees. The other is to record the values separately for nodes and branches. UCT is proved to converge to the optimal solution if the values stored in nodes are used for *mean term* and values of the branches are used for the *bias term*, as shown in the right of Fig. 13.

Implementation Techniques

Here is a list of common components and techniques for modern Go programs:

- Fast data structures for Go board, including block and pattern information.
- Fast pattern matcher including simple 3×3 matcher and heuristic features needed in both machine learning phase and playing phase.
- Machine learning methods.
- Zobrist hashing for fast hash value calculation.

- Game database used as training data for machine learning and opening book construction.
- Time control for playing games in tournament.
- *Pondering* (thinking while the opponent is thinking) and tree (or hash table) reuse.
- Dynamic *komi*. Especially important for handicapped games. Adjust virtual *komi* to avoid playing too safe (too aggressive) moves.
- Using the results of tactical searches such as capture search or life-and-death search.
- Opening book.

Concluding Remarks

Current Computer Go Strength

N. Wedd maintains a Web page titled "Human-Computer Go Challenges" (Wedd 2015). After the invention of MCTS, strength of Go programs improved rapidly. From 2012 to 2014, strongest Go programs (Zen and Crazy Stone) have played several 4-stone handicapped games against professional players including former champions (4-stone handicap means approximately 4-dan difference.) The results include similar number of wins and losses.

Discussion

Before the invention of MCTS, Go was regarded as a grand challenge of game AI research because of the difficulty. The difficulty of Go led to the invention of an epoch-making algorithm, Monte Carlo tree search. Many MCTS-related researches exist both in theory and application and in game and nongame domains. Still, Go is the most intensively studied target for MCTS.

There are many studies about search algorithm and machine learning, which is combined with many implementation techniques. Many researchers are working how to exploit increasing computational power of recent computers. Recently, at the end of year 2014, the first success of deep learning approach for Go was reported. Deep learning could be the candidate for the future breakthrough. It is still in early research phase, but the results seem promising.

Computer Go is improving rapidly and it is difficult to predict even in the near future. At least for some more years, Go is likely to remain as one of the most interesting challenges in game AI.

Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being

Anthony L. Brooks
Aalborg University, Aalborg, Denmark

Synonyms

Biofeedback; Gamification; Gesture motion; Healthcare; Rehabilitation; SoundScapes; User interaction; Video games

Definitions

Biofeedback	A sensing and response system that sources physiologic human data (typically using sensors on- or off-body) mapped to selectable content (typically digital) as feedback to self-inform participants of their input consciously, subconsciously, or subliminally. Often used in treatments to teach patients to modify specific physiologic functions.
Gamification	Application of game elements within a typically nongame context. Contextually, in this case [re]habilitation, healthcare, and interactive performance art, targeting participant motivation, immersion/engagement, and playfully rewarding positive experiences offering inclusive well-being. (Regaining skills, abilities, or knowledge that may have been lost or compromised as well as helping disabled people attain, keep, or improve skills and functioning for daily living – in line with the Convention on the Rights of Persons with Disabilities (CRPD).).
Gesture Motion	Movement of the limb, torso, or whole body within a sensing space.
SoundScapes	Contextually specific referring to an author-conceived bespoke accessible, inclusive, and interactive multimedia environment targeting, through adaptive personalization, creative expression, and playful interactions alongside user experiences of enjoyment, fun, and entertainment. Utilized as an alternative intervention concept in healthcare and rehabilitation to improve participation in treatment programs. The concept is informed from the author's audiovisual art.
Video Games	Computer graphics and sound elements comprising a "virtual environment" within which players interact (via an input device) with typically animated objects displayed on a monitoring device for the sake of entertainment.

Introduction

As Tolstoy stated in "What is Art?" (Tolstoy 1995 [1897]) – *Art is a human activity consisting in this, that one man [or woman] consciously by means of certain external signs, hands on to others feelings he has lived through, and that other are infected by these feelings and also experience them*. In the text he states how *art is a form of consciousness*, framing in so doing the

essential role of art as a vehicle of communication and empathy.

On a more recent note than Tolstoy, Grau (2003) posited: . . .*ultimately, it is the intellectual vision, transposed into the work step by step with technology as its reference, that remains the core of a virtual work of art*.

This article introduces a body of work where the catalyst is creative expression and playful interactivity. The author's background as an artist is prevalent in how empowerment via embodied interaction utilizing digital technologies (predominantly sensor-based [on-body/off-body] biofeedback mapped to digital multimedia [auditory, visual, robotic stimuli, etc.] and analogue content [video feedback, vocals, etc.]) was identified as a means to supplement traditional intervention in specific healthcare treatment programs and (re)habilitation.

Within the work a commercial industry startup was realized from the author's research, as well as international and national funded projects, and global acclaim as, e.g., plenary keynotes at leading international conferences, and more.

This contribution is focused upon sharing how in the 1990s, for approximately a decade, computer graphics were created as gesture-based interactive games under the author's gamification (including social interaction, creative expression, and enjoyable play) approach to healthcare and rehabilitation intervention. The core of the strategy is a catalyst fun experience from within an openly adaptive interactive environment that can be tailored for each participant profile and the treatment program goals. Most recently the work has realized a series of publications under the theme of "Technologies for Inclusive Well-Being."

Background

The work originated as an alternative contemporary avant-garde "human-at-center" art-related creative expressive form (i.e., "human-as-art"). Following numerous proof-of-concept and feasibility testing, early apparatus and method were realized in performances and exhibitions with positive reactions. In other words, the author-developed sensor-based bespoke systems were primarily explored within the author's work of own stage performances at numerous national and international festivals (including televised performances). These explorations included instances where he directed and produced (e.g., Cultural Paralympiad [Atlanta 1996 at Rialto Theatre]; Cultural Olympiad and Paralympiad [Sydney 2000 at Homebush arena]; European City of Culture [Copenhagen 1996 at Arken MoMA and Avignon 2000 at Cafe Nine]; Danish NeWave New York at Gershwin, 1999; Scandinavian Museums of Modern Art exhibition tours 1995–1999; and other "art-related" settings, e.g., Roskilde Festival 2000 and more). All instances were targeted as research resulting in ongoing learning of system limitations, potentials, and possibilities toward the envisioned applications beyond solely traditional "art" forms. In other words, in the majority of cases – for example, inclusive or adjacent to the above listed events – demonstration workshops, hands-on tutorials/seminars/symposiums, or other accessible showcase forms were arranged at the author's initiative to present the "alternative art" application, i.e., in healthcare, rehabilitation, and therapeutic training intervention. Such additional events offered increased research and learning opportunities including reviews, appraisals, assessments, and evaluations across disciplines, nationalities, and end users.

Bespoke Systems Overview: Leading to Patent - see Brooks and Sorensen (2005)

Overviewing and simplifying, the systems consisted of on-body and off-body systems that were experimented having differing biosensing profiles. Thus input was sourced ranging, for example, from inner-body micro-electrical signals, through limb or whole-body gestural position and motion dynamics, to spatial environmental signals where human occlusion or signal generation results in system input. Thus, human gesture attributes (proprioceptive, kinaesthetic, and related dynamics) and human state (being,

emotions, etc.) acted as input. Sourced input signals are routed to selectable software for mappings (scaling, filtering, etc.) to impact feedback responsive content (typically digital). This process routing of the data signals is managed to align desired relationships, i.e., interactive/reactive toward a goal of achieving flow, aesthetic resonance, self-agency, efficacy, and related idiosyncratic human attributes via afferent/efferent neural feedback loop closure. This causal loop closure is achieved through the process of optimally tailoring system attributes to human attributes, e.g., where the designed challenge is matching user satisfaction and sense of achievement. Individual end-user profile assessment can be either formal (with therapeutic input to realize targeted preset steps) or improvised (through system operator's – usually the author – experiences, so more impromptu adjustment of change parameters) to impact the system session design as experienced by a user. See Brooks Patent US6893407B1 on method and apparatus.

Embodied Interaction

The designed embodied interaction considered intent and non-intentional input as well as conscious and unconscious innate attributes. Through these means control and non-control have been experimented Brooks (2004, 2018).

Self-reflections and self-critique included from first-person and third-person experiences through which the system developed as a substantiated open and adaptive entity. As such the system (apparatus and method) enabled adoptions of various technologies as they appeared as both input interface apparatus and content toward optimizing a used model for treating a range of patients including those "born with" impairment or those who had "acquired" impairment either through accident, incident, or disease.

Experience as Product

A goal behind the "human-as-art" performative inquiries with the system was to realize a new instrument or tool that could supplement in and across rehabilitation and healthcare contexts. The concept was to explore creativity and play as motivational human modes attempting to make the experience of treatment/training more enjoyable, fun, and stimulating to participate within and less mundane, tedious, and boring. Once the system had reached certain maturity, further reflections and critiques resulted in system improvements that aligned with external professionals who evaluated from a formal and professional therapeutic perspective. Over the many years, the family and friends of users also evaluated – albeit in a more non-formal/informal context.

A motivational intervention (in-action) model and an (on-action) evaluation model were developed and published to support practicing professionals and/or home use by families and carers or even in self-use Brooks and Petersson (2005).

Exploring Nuances of Differences

An ongoing vision was of creating, utilizing, and exploring digital technologies to explore aspects of interactions such as nuances of differences that may be apparent through dysfunction compensatory requirements (e.g., an augmented sense of hearing/touch if a person cannot see). An evolving interest from this vision is in the exemplification and integration of such finite sensorial differences and how they can be represented and utilized within the art-related works for wide-audience education and enjoyment. In other words, and for example, how an "artist" with heightened sensory attribute (through loss of other sense) can represent such a sensory nuance so that audience members who are fully sensory loaded (thus, potentially, not as highly nuanced in a specific sense) may appreciate the art and be provoked to reflect on their educating of their evoked sense via the artwork.

This compensatory approach questioning comprehension of alternative channelling to augment training and other benefits from creatively expressing was apparently original within rehabilitation fields. For example, the applied research

with acquired brain-injured patients in a clinical setting questioned how a sense of proprioception (a participant's body sense of its parts and relative location to its other parts and the effort exerted in motion often related to balance and/or neglect) that was damaged could be "trained" through a patient *listening* to or *seeing* where their relative position of their own parts of the body are instead of *feeling* it. Additionally, patient dynamics of kinesthetic awareness of the position and movement of their parts of the body by means of their proprioceptors is targeted through programmable thresholds in the digital content algorithm according to a patient profile. Interactive computer graphics were thus engaged, alongside other digital content, as a means to visually inform a user of system input.

Afferent/Efferent Neural Feedback Loop Closure

Afferent/Efferent Neural Feedback Loop Closure: Proprioception and kinesthetic awareness are key aspects of the concept presented herein.

Literature informs that the central nervous system (CNS) receives sensory stimuli as (afferent) impulses external to the body. It then sends appropriate (efferent) instructions to a person's muscles and joints on how to react. The brain also receives some messages that cause the body to react unconsciously. Proprioception is a term referring to the internal messaging (the central nervous system) driving and controlling motion actions. Proprioceptors are sensors in human joints, muscles, and fascia, providing information needed to produce coordinated movement. Kinesthetic awareness refers to our ability to navigate space and the awareness of how we move. Kinesthetic awareness and proprioception work as partners to get us through the movements of our lives from the inside and the outside of the body. Muscle memory is a kinesthetic concept. So many things that we do without thinking – such as walking, whether we do it correctly or not – are kinesthetic experiences based on proprioception, which provides the awareness of our joints and body in space. Proprioception and kinesthetic awareness decrease after an injury – although, your brain will still have the skills stored within, so it is easier to relearn them. Even though your strength may come back easier, you will still need to spend time improving your proprioception and kinesthetic awareness so that you can fully recover.

By employing a system that responds to motion within an invisible space that can be controlled for data inhabitation and also mapping to digital content as stimuli offers opportunities in learning through feeling such as a sense of body position, muscle movement, and weight as felt through nerve endings.

Cognitive aspects are also involved.

Technologies for Inclusive Well-Being

Within the ongoing research, the art informs the design and intervention in rehabilitation in a cross correspondence such that the intervention also informs the art. This is aligned with reconceptualization, reframing, and cross-domain mapping as a bilateral approach that has been found effective in developing the research to the next level; however, that is not elaborated herein as it is a subject of another publication. Suffice to say that holistically, the research targets societal impact in (re)habilitation and healthcare under an umbrella titled "Technologies for Inclusive Well-Being" under which a number of publications have resulted with the author as lead editor. The next section introduces the author's gamification intervention approach.

Computer Feedback Training Under Gamification Approach

Near the time when biofeedback was being explored via worn sensor systems, audio-visual computer feedback and a series of robotic light devices were applied under a gamification approach to training in (re)habilitation and healthcare as outlined in the previous section. The purpose of this approach to supplement traditional approaches in intervention within training treatment programs was to engage the participant

to enjoy the training (vs. mundane, boring, and repetitive exercising without any self-reflective feedback that informs of progression).

Fun, Play, and Creative Expression Leading to Aesthetic Resonance

Fun, play, and creative expression are keywords in this approach that stimulate self-efficacy, self-agency, and a concept coined as aesthetic resonance that was the subject of European projects around the millennium (see Brooks 2011). In these externally funded projects, a focus was on creating systems where there was not the need for patient preparations such as careful positioning of sensors, the use of conductive gel to improve signals, and other invasive aspects. A patient could simply enter a space, set up an interactive environment, and move to manipulate digital responsive content. Initially the content was audio due to the used MIDI (Musical Instrument Digital Interface) signal protocol being native to communication within the music/sound domain. However, within the applied research sessions, it was clear that a wider selection of digital content to stimulate participants was required. Due to the author's background in mainframe computers (e.g. Honeywell TDC 2000), a decision was undertaken to investigate computer-based video games and interactive graphics (Figs. 1, 2, and 3).

Figure 1 illustrates interactive light gobos and Figs. 2 and 3 a "body paint" algorithm developed under a European project based on the author's research titled CAREHERE (Creating Aesthetic Resonant Environments for Handicapped, Elderly and Rehabilitation). The algorithm was used within the project and beyond, including in the author's annual workshop hosted by Casa da Musica, Porto, Portugal, which was a small part of a larger festival for disabled participants organized by the education team at the venue. Over a 2-week period, a variety of groups with differing profiles attended morning and afternoon (two workshops daily). Age ranged from young children to elderly and across the spectrum of dysfunction, both physical – including deaf, visually impaired, and wheelchair bound – and mentally challenged. Body painting was one of the activities whereby "digital paintings" were created as graphical images in the computer through participants' dynamic movements and then printed as an A3 picture. The pictures were exhibited as shown in Fig. 4 for the duration of the festival and given as gifts to the authors upon cessation. Notable was how, even though the pictures were in abstract forms, on return to collect their created artifact following the end of the festival, the participants each identified their own creation and collected it from the exhibition wall. It was astounding as there were no names visible for such identification of the computer graphics.

In this simple exercise, it was clear how a tangible outcome meant so much for the participants. When using auditory feedback, there is no tangible outcome unless a recording is made

Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 1 The author's gesture control of Martin Lights graphics – SoundScapes at Olympics and Paralympics, Sydney 2000 via three-headed infrared sensors mapping via MAX to DMX 512 via translation control interface

Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 2 Image of head and hand painting by PMLD participant

Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 3 Full-body painting based upon activity-level threshold mapped to color chart

and given on USB stick or download. The design was thus a success for participants and the organizing staff who attended with the groups. On return 4 months later for a conference, the leader of the elderly home for mentally challenged/dysfunctional attendees of the workshop informed that the institute organized an exhibition and oral presentation event so that the elderly could tell their own stories about creating their paintings. She explained how their motivation and inspiration had been stimulated to a highly positive degree such that their stories, unusually remembered compared to their other living detail, detailed aspects that her staff did not realize. She explained that it was a moving experience for the families who attended.

Soon after the mid-1990s, investigations of interactive animations and gamification within the SoundScapes research were conducted. This preceded the Personics interactive computer graphic environment that is introduced next.

Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being,

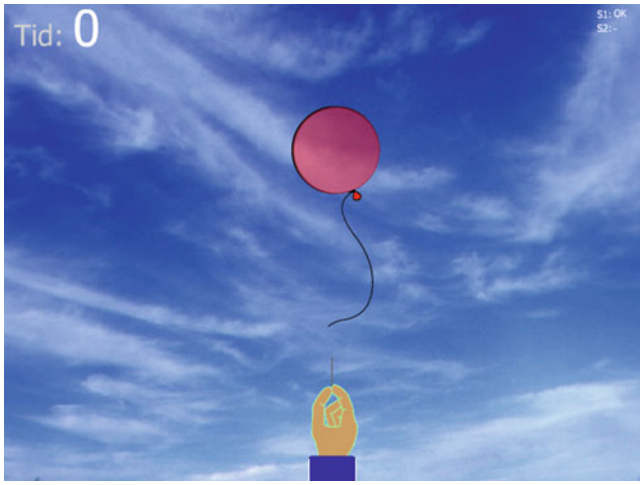
Fig. 4 Eyesweb body paint exhibition, Casa da Musica, Porto, Portugal

Personics

Experiments within the research led to a first simple "game" as an animation of an airplane that could take off, fly, and land with control via unencumbered gesture (i.e., no mouse, joystick, or keyboard). The reader should be aware that this experimental use of games controlled with gesture technology was before the pervasiveness of games and gesture control peripherals in the early 2000s.

The simple images on the following pages indicate the further explorations of basic interactive environments developed with the software Macromedia Flash (later Adobe Flash) as game content under the commercial company Personics as animated computer graphics as gamification in (re)habilitation therapy. The development was across the two funded aforementioned national and international projects having similar goals. In one case, the development followed input from the Humanics (the Danish government project) research team from the Center for Rehabilitation of Brain Injury [CRBI], this being where the clinical location of patient training was based at the University of Copenhagen. The team was working with acquired brain injury patients. Author-led roles in the project included conceptualizing, iterative design, leading intervention sessions, and communicating proposed designs and refinements with the development team, alongside testing and troubleshooting prior to sessions. The research personnel included a neuropsychologist, a psychologist, a cognitive psychologist, and a physiotherapist that worked under the Danish government *Erhvervsfremme Styrelsen* (Danish – translated as business development agency) who funded the research project titled Humanics for 9.5 million Danish Kroner (DKK). Another Danish government body, named *Satspuljen*, funded the project for an additional one million Danish Kroner (DKK).

Parallel to this project was the aforementioned international project. The background of this project is the research resulted in a European Union probe (under the European Network for Intelligent Information Interfaces – www.i3net.org). This was a funded project titled "The World Is As You See It" (TWIAYSI) – with the University of Bristol and a Swedish partner. TWIAYSI was developed into a European funded Framework V IST Key Action 1 project supporting the program for applications relating to persons with special needs including the disabled and elderly titled CAREHERE (Creating Aesthetic Resonant Environments for



Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 5 [Balloon] Computer graphic with gameplay receiving arm motion from the participant to reach and puncture the balloon with the pin in the animated hand. Time to complete the task in upper left

Handicapped, Elderly and Rehabilitation) Funding was approx. €2M.

Personics was invited by the author to participate in both projects.

Under the sponsorship of IBM at the World Congress for Physical Therapy (WCPT) in Yokohama, Japan, the author presented his research paper titled "Virtual Interactive Space (V.I.S.) as a Movement Capture Interface Tool Giving Multimedia Feedback for Treatment and Analysis" (Brooks, 1999).

Approximately a decade later, Hagedorn and Holm's (2010) independent randomized intervention study questioned traditional training versus computer feedback training (system resulting from author's research). This is reported in the *European Journal of Physical and Rehabilitation Medicine* where results state impact gains of up to 400% illustrate potentials from using selected games in Virtual Interactive Space as published in Brooks' 1999 paper. The 2010 investigation is introduced after the next section that presents the simple interactive computer graphics used.

Personics Computer Graphics

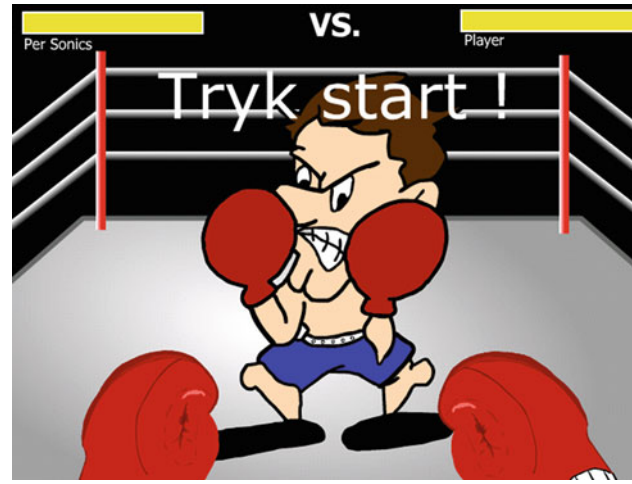
The following images represent the gameplay graphics. Notes attempt to describe the gameplay and target in the therapeutic sessions with bmp screenshots depicting start screen and interactions.

Figure 5 illustrates a balloon game concept where a sensor is placed at a specific location according to therapist input. In Hagedorn and Holm (2010), balance training exercise was for each patient to alternate between normal standing balancing and toe-standing balancing. Balloons were popped when each cycle was completed within the sensing space. Duration of training depended on patient endurance. The number of balloons popped gave indication of training effort.

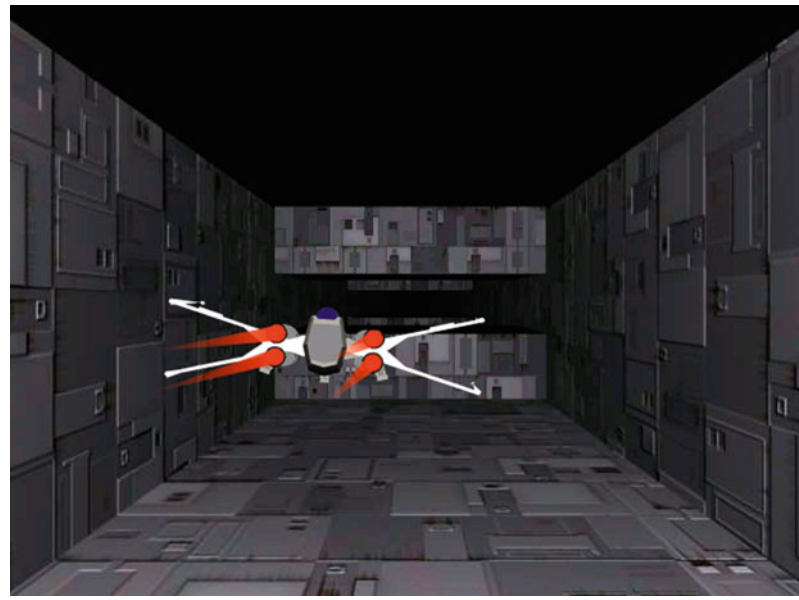
Figure 6 was a boxing game tracking the patient's two hands (mapped to the lower boxing gloves). Scores were archived according to performance.

Figure 7 was a game where the navigation of a Death Star fighter (Star Wars) was controlled by patient movement. Guidance through a maze was tasked.

Figure 8 was a Dolphin wireframe model that was mapped to two sensors representing horizontal and vertical travel. This is used successfully in the CRBI research where a therapist controlled one sensor and a patient controlled a second sensor. Progression for the patient was to use both sensors to control the full travel of the dolphin. Time was recorded for each level and a number of fish caught. Levels were progressively more difficult whereby lethal jellyfish had to be eluded.



Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 6 [Boxer] A two-handed exercise where sensors detect dynamic motion of each hand, which are mapped to left and right boxing gloves to strike opponent who is able to guard and strike back



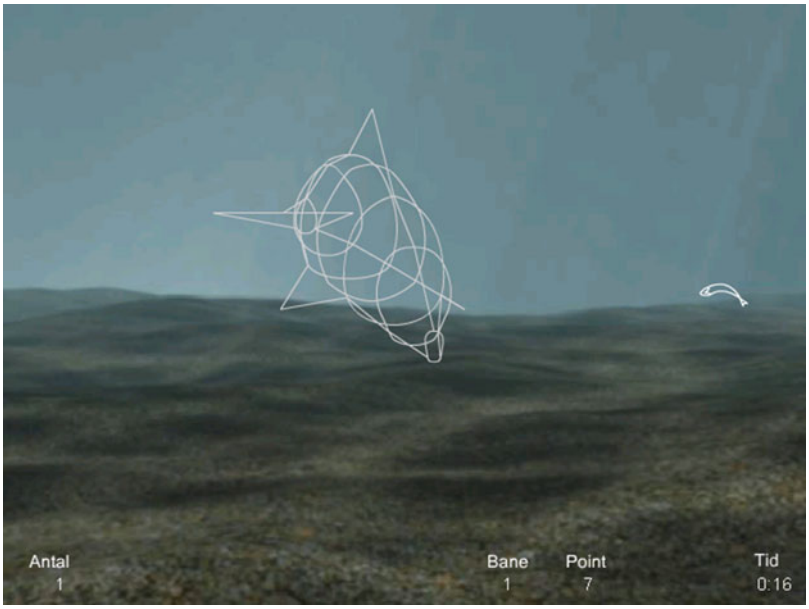
Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 7 [Death Star] Flight simulator where participant motions control up-down (y-axis) and left-right (x-axis) of Death Star fighter vehicle to prevent crashes and to reach targeted goal

Figure 9 was used to task the patient in dynamic motion aligned with a weightlifter raising a dumbbell. Dynamic of motion was tracked within the sensing field.

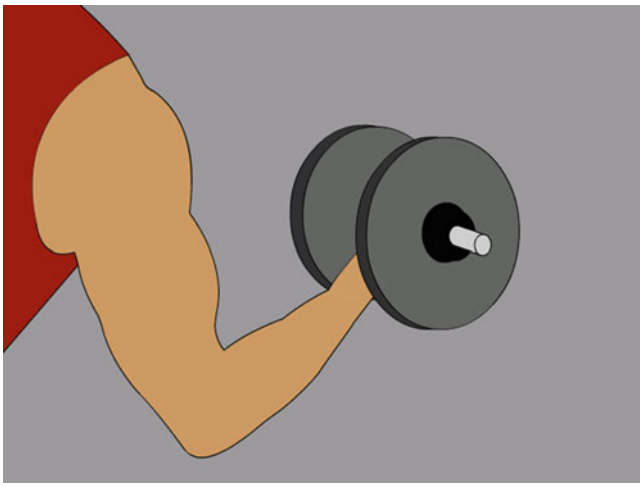
Figure 10 was themed from the Mission Impossible film where a diamond was stolen. Patient activity was through three sensor fields that would activate, deactivate, or alarm the system. The mapping of this game was mostly found to be too complicated for most patients.

Figure 11 illustrates another dynamic motion computer graphic. In this case the patient's hand motion had to exceed a threshold in order to let go of the ball. This proved a favorite exercise for acquired brain-injured unilateral neglect or hemispatial neglect patients training a damaged side.

Figure 12 illustrates the tower that was one of the animated games used in the Hagedorn and Holm (2010) study with balance elderly patients. The number of blocks and difficulty could be changed and archived. Feedback of balance in training was where one leg was lifted from the ground – as in stepping actions associated with



Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 8 [Dolphin] Wireframe dolphin travel controlled by two sensors mapped to x-axis and y-axis to catch and eat the dead fish dropping from top of the screen while escaping hazards on each level



Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 9 [Dumbbell] Sensors capture participant lifting motion dynamic and range to raise a corresponding animated dumbbell held by a weightlifter

walking activity within the sensing space. The height of the built tower indicated training effort. Both legs were trained.

The waiter tray game, as illustrated in Fig. 13, was also used in the Hagedorn and Holm (2010) study. Sensors captured body position and adjusted the tray angle accordingly. Patients stood on a firm plate, which was placed upon a 5 cm depth of dense foam. The numbers of broken glasses were recorded in each session of 2-min duration. A session consisted of two instances of training where both data were included for analysis. Physical level-of-difficulty adjustments took the form of a thicker foam plate that could additionally be changed for a tilting board; also glass friction and plate size were adjustable.

Figure 14 gives a direct feedback to a patient's balance according to a horizontal line that was required to line up to the central division in the graphic.

The fourth game used in the training was where balance controlled the position of an animated empty basket to catch images of fruit falling from a tree. Healthy fruit was collected, while

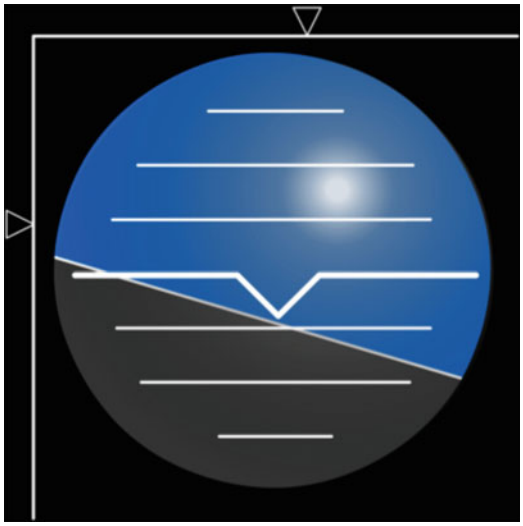
The goal is to keep the glass on the tray and train dynamics. Tray size and friction coefficient can be adjusted

rotten fruit was not. Each incremental level had increasing speed of fruit falling.

Discussion

Eber (1997) reflects how a work of art, according to Tolstoy (1995 [1897]), is sincere, and it transmits feelings through lines, colors, sound, or words. The feelings embedded in the imagery start with the creator and the creative process. The work may take any form, but to be art, the object, idea, or installation goes beyond the physical and contain some form of human experience. Art may be created with any tool, as long as the artist rises beyond that tool into an experiential realm. Many



Computer Graphics, Video Games, and Gamification Impacting (Re)Habilitation, Healthcare, and Inclusive Well-Being, Fig. 14 [Balance] Motion sensors combined to perform as a mouse emulator driven by weight distribution. The goal of the participant, typically with acquired brain injury, was to position the dividing horizontal line along the central balance. Arrows on the y-axis and x-axis act as guides

have debated the existence of the creative domain with the computer art medium, especially virtual environments (VE). With the tools to create a VE, the artist will learn a new technology that may influence the nature of and how she reaches the creative level (see Eber 1997).

According to Eber (1997), in addition to the acquisition of new information, the artist who chooses to work with VEs also has a new set of aesthetics to consider, as the final work of art is wholly different from that using any other medium. Contrary to the concepts expounded in the popular media, a VE art installation can be more than a display arena for the art of others (e.g., Picasso) or a "shoot 'em up" computer game. It can be a work of art in and of itself, one that requires of the artist the same level of abstraction into the spirit of creativity as any traditional medium demands. How and at what point does the creative process happen for a VE artist in a world of computer peripherals and code?

Further Eber (1997) states how an art installation is a work of art that goes beyond an object that exists on a wall or behind a glass but encompasses an infinite number of artistic possibilities including alternative presentations, environmental constructions, multisensory stimulation, viewer interactivity, and theatrical performance.

This text presents a historic perspective of the research alongside a review of the basic computer graphics that resulted. The purpose of the text is to share the narrative while attempting to inspire next-generation researchers. The goal to inspire targets championing others to persevere against adversity, often when being mocked when pursuing one's original concept, in this case a concept that resulted in national and international funded projects, a patented method and apparatus, commercial industry product, and company start-up.

Early studies explored solely auditory stimulus as a feedback to user input. Initially the means of input was hardware-based rocker control pedals as typically used by musicians for altering instrument output, e.g., guitar. Subsequently, user biofeedback signals were sourced either via on-body or off-body sensing interfaces with differing profiles. Such profiles have increasingly advanced over the years of the research such that original interfaces are no longer viable when compared to affordable and available computer game peripherals and camera-based solutions.

However, the "communication method and apparatus" patent has been referenced 16 times, including 12 by the patent examiner.

A further example of impact is an independent investigation of product resulting from this research in a randomized intervention study by Hagedorn and Holm (2010) comparing conventional balance training against computer feedback training with older people. The randomized controlled 12-week intervention trial was designed on pre- and post-training evaluations conducted on 35 outpatients of a geriatric falls and balance clinic. Responsive computer graphics, with a variety of selectable game themes, responded to input motion sensors.

Results were reported of 400% improvement in specific performance; however, in the author's opinion, the industry is still lacking behind

in training trainers to fully optimize such results within a wide range of interventions so as to benefit societally via transfer to activities of daily living (ADL).

Conclusion

This article shares insight of avant-garde art with societal impact that has been recognized by third-party researchers and educators as pioneering the use of digital technologies with differently abled. A focus has been on illustrating the simple computer graphics used as mappable content to give feedback selectable from an array of stimuli. This text informs how the healthcare rehabilitation informs the art and correspondingly how the art informs the healthcare rehabilitation.

The use of multimedia responsive feedback to human input indicates how art (creative expression) and play (enjoyment and fun) have an important part to play in both physical and cognitive therapy (re)habilitation. While extended range and dynamics of motion (body, limb, etc.) are quantifiable, it is also evident through the comprehension of designed interactions by profound and multiple learning disabled (PMLD) how the concept has potentials beyond what has already been reported.

To sum up and in accord with these conclusions, it is important to point out how it is increasingly evident that improved systematic evaluation is needed in this field to define the specific use benefits of (computer graphics as) video games in healthcare and rehabilitation intervention. Aspects of such evaluation are proposed as incorporating increased duration and control of trials with improved measurements (randomization, blinding, etc.) and consistency of measurement tools across investigations including beyond actual treatment programs to embrace impact on activities of daily living (ADL). However, innate to such a proposal are the ongoing challenges of individual human differences that many may consider immeasurable; yet, for improved research and impact comprehension, it is important to target optimized research validity and reliability in order to advance and educate.

Notes The figures (5 – 14) are from the author's own archive from employment. All efforts to get permission have not been responded upon and it is understood that the company was closed shortly following the author's departure and copyright ownership is not listed for these images. Acknowledgement made in this chapter for the authors of the images created under the company Personics who do not name or credit authorship.

Definition

Conceptual model of mobile augmented reality for cultural heritage towards enjoyable informal learning is a representation that provides, by a composition of concepts, component of content, navigation and user interface design, interactivity, features, hardware, and process that is appropriate for enjoyable informal learning at cultural heritage site for mobile augmented reality.

Introduction

Mobile augmented reality (AR) for cultural heritage site has been developed for already a decade (Angelopoulou et al. 2012; Armanno et al. 2012; Chang et al. 2015; Ciurea et al. 2014; iTACITUS 2007; Kim and Park 2011; Moorhouse et al. 2017; Seo et al. 2011; Techcooltour 2013; Tussyadiah et al. 2017; Vlahakis et al. 2002). However, these existing applications lack enjoyable informal learning concept (Damala 2009).

Enjoyable informal learning is based on interpretation theory (informal learning in cultural

heritage) and enjoyment theory. Enjoyable informal learning enables visitor not to feel he/she is learning, but at the same time, he/she is achieving new knowledge (Ariffin 2009). However, the existing mobile AR for cultural heritage site lack major components in enjoyable informal learning, namely, navigation and user interface, quality of content, use of questions, and physical orientation (Bellotti et al. 2002; Moscardo 1996). This is critical as it can make the usage of mobile AR as interpretive media to help visitor to learn at cultural heritage site is far from being practical.

Therefore, this entry shows how a conceptual model, which provides component for enjoyable informal learning at cultural heritage site (Pendit et al. 2014), can be used to design AR applications for cultural heritage sites. A conceptual model represents the key concepts and provides accurate, consistent, and complete representation of concepts (Churchill 2007; Norman 2014). It helps developer to develop mobile AR that implements enjoyable informal learning at cultural heritage site that enable visitor to learn at cultural heritage site in enjoyable way. It helps developer to develop mobile AR that implements enjoyable

Expert 1 (Spain)	(a) Divide "media elements" into two types: passive and active content. Active content is the content that includes user interaction, such as: activity, social interaction, and games
	(b) More details on the theory to understand their relevancy on supporting the content structure
	(c) Put elements in mobile technology into categories: "core technologies for AR" and "necessary devices for AR." The terms "sensor" and "mobile technology" are also not proper
	(d) Add "taking picture" and "interacting with content" in the "Activity" component
	(e) The term "chat" in social interaction is not proper
	(f) Add virtual views in the presentation style
	(g) Strength: the conceptual model is feasible and worthwhile to improve the informal learning experience at cultural heritage site
	Weakness: Most of components have been presented in previous works and novel components in informal learning are not sufficient
	(h) Add details for each component in hierarchy or layers than list the individual elements
	(i) Validate the conceptual model through user evaluation
Expert 2 (France)	(a) Add more detail explanation on content structure and theory
	(b) Relationship between components in "mobile technology" is not understandable
	(c) Add category for different "function" of component and add "Display" component
	(d) "Activities," "navigation," and "manipulation" can be added as well as "activity" related to media elements: "see and hear" in activity component
	(e) Add "navigation for museum and indoor cultural heritage environment."
	(f) Add shared view with single display in social interaction
	(g) Provide other type of games: 3D puzzle
	(h) Provide more explanations in "presentation style"
	(i) MLT theory and collaborative learning theory should be linked to other elements in the content structure
	(j) Mindfulness theory should consider personal cognitive style and traits of visitor that may influence the social interaction. Constructivism theory, situated learning theory, and experiential learning theory should be linked to media elements
Expert 3 (Spain)	(a) Consider HCI theory as AR system should be interactive in real time (Azuma 1997)
	(b) Differentiate between audio and sound in media elements. Also distinguish different types of object: static and dynamic. The elements also can respond to user interaction
	(c) Consider providing a complete map of the site and recommended route for the visit in navigation
	(d) Clarify the term "chat." Differentiate between virtual and real (face to face) interaction in social interaction
	(e) Clarify the term "separated augmented view" in presentation style
	(f) Add category for different function of each mobile technology component, such, hardware, software, and process
	(g) Conceptual model is well presented and logical. However, it misses the term "interaction" as it is a fundamental part of AR system. The mobile technology component also needs to be better presented
	(h) Consider to add validation/evaluation component in content structure on evaluating the learning process
Expert 4 (Taiwan)	The proposed model is thorough and detail. I expect the outcomes of this model would be good if the learning activities can be well-arranged
Expert 5 (USA)	(a) Useful conceptual framework to inform the design. Mindfulness theory is not familiar but others are well aligned with the teaching and learning methods possible through AR
	(b) The missing major element is the outcome of the variable that will be measured
Expert 6 (Malaysia)	(a) Proposed elements in content structure are too generic and are applicable to any kind of applications
	(b) Connections of all theories ad components are somewhat logical
	(c) The conceptual model is partly usable to the development of AR for cultural heritage toward enjoyable informal learning
	(d) The conceptual model is too brief
	(e) Expand and detail out specifically about AR and cultural heritage
Expert 7 (Malaysia)	The conceptual model is good but the scope is too wide that it should focus more on enjoyable learning

informal learning at cultural heritage site that enable visitor to learn at cultural heritage site in enjoyable way. Since the conceptual model has been developed (Pendit et al. 2014), it was then evaluated and revised through series of evaluations, expert review, field study of enjoyable informal learning, focus group discussion, and review of related conceptual model of mobile AR for cultural heritage site and mobile guide. After all those evaluations, the conceptual model

was finally finalized which are presented in the end of this entry.

The topics of this entry are consisted in four sections, which are introduction, methodology that tells about validating the conceptual model, the revised conceptual model that becomes the result of validation, and finally, at last, the conclusion of the study.

Methodology

Basically, the conceptual model has validated through two steps: expert review and focus group discussion. Expert review involved seven experts to validate model based on review form through email communication. After the expert review, before continuing with the focus group discussion, the researcher embarked on a field study of enjoyable informal learning content at cultural heritage site in order to respond to review of expert on the novelty of component of conceptual model. Then, after the component of conceptual model was reviewed based on user requirement of enjoyable informal learning content from field study's result, it was sent to focus group discussion. The focus group discussion validated the model by joining seven experts. Then, after it has been evaluated in focus group discussion, an activity called review of the conceptual model of mobile AR for cultural heritage site and review of mobile guide was completed to act in answering focus group discussion's feedback about the component of conceptual model. The result from the review was applied in revising the conceptual model of mobile AR for cultural heritage site toward enjoyable informal learning. At the end, the final version of the conceptual model was produced.

Expert Review

In validating the conceptual model, expert review was conducted. There were seven experts who had reviewed the conceptual model with criteria of teaching AR/human computer interaction/

Conceptual Model of Mobile Augmented Reality for Cultural Heritage, Table 4 Comments from focus group experts

No.	Comments
Expert 1	a. Include informal learning theory
	b. Emphasized on interactivity and enjoyable informal learning for content element component
	c. Connection in conceptual model could not be seen
	d. Focus more on enjoyable informal learning and the main contribution of conceptual model
Expert 2	a. Theories are relevant but have to be presented more clearly
	b. Add informal learning theory
	c. Consider "tangible AR" for terms
	d. Add interaction component
Expert 3	a. Connect the mobile AR technology and content element component
	b. Add more elements in content element
	c. Create general model to be used for other field related with mobile AR or enjoyable informal learning or cultural heritage site
Expert 4	a. Connection between all components should be improved
	b. Focus more on enjoyable informal learning
Expert 5	a. Mobile AR technology component should be improved
	b. The terms should be improved
	c. The connection between mobile AR, theories, and content element is not clear
	d. The conceptual model is not clear enough
Expert 6	a. The theory should be reconstructed in order to be understood
	b. Consider to combine content element with mobile AR technology
	c. Some terms are not clear, such as, "provided for each site"
	d. Combine all components with mobile AR technology
	e. Differentiate the uniqueness of mobile AR technology component from the existing one
Expert 7	a. Add one element special for cultural heritage site in content element
	b. Connection between theory and content element seems logical
	c. The term "registration" is not clear
Expert 8	Create general model consists of three main topics: mobile AR, enjoyable informal learning, and cultural heritage site

multimedia with minimum 5 years of experience. The expert was given a copy of proposed conceptual model with the form that contains check list of items and elements of conceptual model. The thoughts from the experts said that conceptual model had terminology that was easy to understand (refer to Table 1). This also applies to the proposed components which are relevant. Overall, experts concluded that the conceptual model is usable in the development of mobile AR for cultural heritage site toward enjoyable informal learning.

The next result displayed written comments which were sent by two experts who did not fill up the form and other five experts who filled up the form (refer to Table 2). Three experts addressed the mobile technology component. They suggested mobile technology should be provided by category to divide different functions of each element. Furthermore, they also added some elements in the content structure component and changed the terminologies. Some comments were changed in terms of diction but the meaning of comment was maintained.

The review was taken into consideration in revising the conceptual model. In addition, one particular comment which mentioned about lack of conceptual model of novel component of enjoyable informal learning was responded by conducting a field study of enjoyable informal learning content that is elaborated in the following section.

Field Study of Enjoyable Informal Learning Content at Cultural Heritage Site

In response to the feedback from expert, a field study was conducted at Lembah Bujang Archaeological Site, Kedah. The purpose is to gather user requirements about content of enjoyable informal learning at cultural heritage site and to define novel components of proposed conceptual model. The questions were taken from the component of conceptual model, the literature, and expert's feedback. In total, there were five participants from targeted ten participants from 17 to 49 years old who participated in the study. The numbers of participants are relatively enough as the researcher has attained similar answer from all participants (Creswell 2012).The questions are in Malay and English language. They are related to

Conceptual Model of Mobile Augmented Reality for Cultural Heritage, Table 5 Component and element of conceptual model

Component	Description	Element	Implementation
Hardware	Physical components needed for developing mobile AR for cultural heritage toward enjoyable informal learning	Handheld devices	Smart phones
			Tablet
Process	Steps or actions needed to develop mobile AR for cultural heritage site toward enjoyable informal learning	Reconstruction	Reconstruct wall of A Famosa into 3D model by using 3DsMax
		Registration	Align virtual object of wall of A Famosa in the real world by tracking user's position and orientation of user's view
		Tracking	Find location of user by using sensor-based tracking, vision-based tracking, and hybrid-based tracking in A Famosa
		Rendering	Generate virtual object/scene and present it to the real environment of A Famosa
		Interaction	Shaking, blowing, rotating, leaning, and nodding the mobile phone and user's head to retrieve information about A Famosa
Content	A set of media representation which consists of criteria that can be a guideline to provide enjoyable informal learning content at cultural heritage site	**3D model** Overlay certain part that is lost	Reconstruct the lost wall of A Famosa to 3D model
		3D character Represent noble people in the past and act as virtual guide	Alfonso d'Alburqueque, Captain of Portuguese, as 3D virtual guide at A Famosa
		Text Provide description in point by point	Profile of cultural heritage site that contains information about history and background information of cultural heritage site
		Image Overlay certain part that is lost	Old picture of the wall of A Famosa, old picture of A Famosa, overlay picture of Alfonso d'Alburqueque, and old picture of war between Portuguese and Dutch at A Famosa
		Provide old picture about the site, noble people, and events	
		Audio Recorded audio presented by narrator who has the same age with visitor	Story that tells how A Famosa was built by Portuguese
		In-depth and special information in 3D animation and video	
		Provide audio with maximum duration in 5 min	
		Sound Provide ambience of the site in the past that can help visitor imagine how the site was	Sound of bomb during the war
			Conversation between inhabitants
			Sound of captain's car

Conceptual Model of Mobile Augmented Reality for Cultural Heritage, Table 5 (continued)

Component	Description	Element	Implementation
		Animation	Story about how the war between Portuguese and Dutch long time ago happened in A Famosa
		Provide in-depth and special information in storyline	
		Use noble people as character	
		Provide animation with maximum duration in 10 min	
		Video	Story about how the war between Portuguese and Dutch happened in A Famosa long time ago
		Provide in-depth and special information in storyline	
		Use noble people as character	
		Provide video with maximum duration in 10 min	
		Push content The type of content that appears automatically when visitor reaches certain area	All elements of content
		Pull content The type of content that should be retrieved	All elements of content
Navigation and user interface design	Navigation and user interface design that helps visitor to learn in enjoyable way at cultural heritage site	Provide thematic path	Provide theme of cultural heritage site based on colonialism era (Portuguese colonialism, Dutch colonialism, British colonialism)
		Provide layered information	Provide description about the structure and construction about A Famosa and continued by history of formation of A Famosa
		Provide one-tap access for frequent menu	Provide "home" button for accessing the menu
		Provide one-handed control	Provide one-handed control for the navigation
		Provide clue for scene with augmented content	Provide clue in balloon to tell there is augmented scene in the area
		Provide shaped button	Provide play button in its shape in order to make visitor easy to access
		Provide quick button to go to main menu	Provide "home" button to the information menu to go to homepage quickly
		Provide big size of font	Provide big size of font on the interface
		Provide appropriate size of content	Provide three-fourth content size for the page
		Provide enough contrast between text and background	Provide white background for black text

(continued)

Conceptual Model of Mobile Augmented Reality for Cultural Heritage, Table 5 (continued)

Component	Description	Element	Implementation
Interactivity	Activity: a set of activities that can trigger the whole learning process at cultural heritage site by integrating the visitors, learning material, and learning environment	Take picture	Provide option to take picture of A Famosa
		Share information	Provide option to share information of A Famosa to social media (Facebook and Twitter)
		Edit/add information	Provide option to add or edit information of A Famosa
		Create notes	Provide option to create notes about experience of visiting A Famosa
		Save information	Provide option to save the information of A Famosa to personal device
	Interaction	Shaking	Enable visitor to shake their phone in order to retrieve the information about A Famosa
		Blowing	Enable visitor to blow the wall of A Famosa to retrieve the information
		Rotating	Enable visitor to rotate their phone to left or right in order to turn the 3D object to the preferred direction
		Leaning	Enable visitor to lean or move the 3D object to left or right
		Nodding	Enable visitor to move the 3D object up and down by nodding his/her head
Features	Personalization: a set of options that can be chosen by visitors in order to display the right content to fulfill their needs	Historical period	Enable visitor to select the cultural heritage site in the range of 1819–1900 or 1901–present
		Interest	Enable visitor to choose the cultural heritage site to be visited based on personal interest
		Range of distance	Enable visitor to select the cultural heritage site within the range (0–5 km, 6–10 km, and 11–15 km)
		Language	Enable visitor to choose the language based on their preferences
	Games: the type of games that help visitor to refresh, stimulate, and make them understand the history	Adventure games (treasure hunt)	Treasure hunt games about history of A Famosa
		Multiple choice quiz	Multiple choice question about history of A Famosa
	Physical orientation: is a set of functions to guide visitor while learning at cultural heritage site orientation	Showing the surrounding interested places	Show other cultural heritage site near A Famosa
		Showing recommended route to the site	Show the route from airport to A Famosa, enable the visitor to search location of A Famosa
		Allowing direction inquiry	Allow visitor to search for route

(continued)

C

Conceptual Model of Mobile Augmented Reality for Cultural Heritage, Table 5 (continued)

Component	Description	Element	Implementation
		Showing direction with virtual arrows overlay on real path	Show direction to A Famosa with virtual arrows overlay on real path from Saint Paul
		Showing map of the site and location of visitors within the site	Show the map of A Famosa and location of visitor within A Famosa
		Showing provided content	Show the provided content in A Famosa
		Showing visited route	Show the visited route at Melaka Heritage Site
		Showing the current position	Show the current position of visitor

the content that is appropriate for learning in enjoyable way at cultural heritage site, including: types of media, navigation, games, activity, and interaction. In total, there were nineteen questions in total with fifteen multiple choice questions and two open-ended questions. The researcher did the field study by approaching random visitors and interview them about the questions while at the same time demonstrating mobile AR feature mentioned in the question. The responses from participants are provided as follow (Table 3).

Focus Group Discussion

Focus group discussion was conducted to evaluate the conceptual model. There were seven experts who had participated in the focus group. The experts were all from Malaysia, and they should be those have been teaching AR/HCI/Multimedia/Media Studies with a minimum of 5 years of experience.

The focus group was started by presentation about the conceptual model. Then experts were asked to review the conceptual model based on the criteria in the review form (refer to Fig. 1). During the discussion, experts were also allowed to ask questions. The process of discussion lasted for one and half hour. It was a beneficial discussion. The result is provided in Table 4.

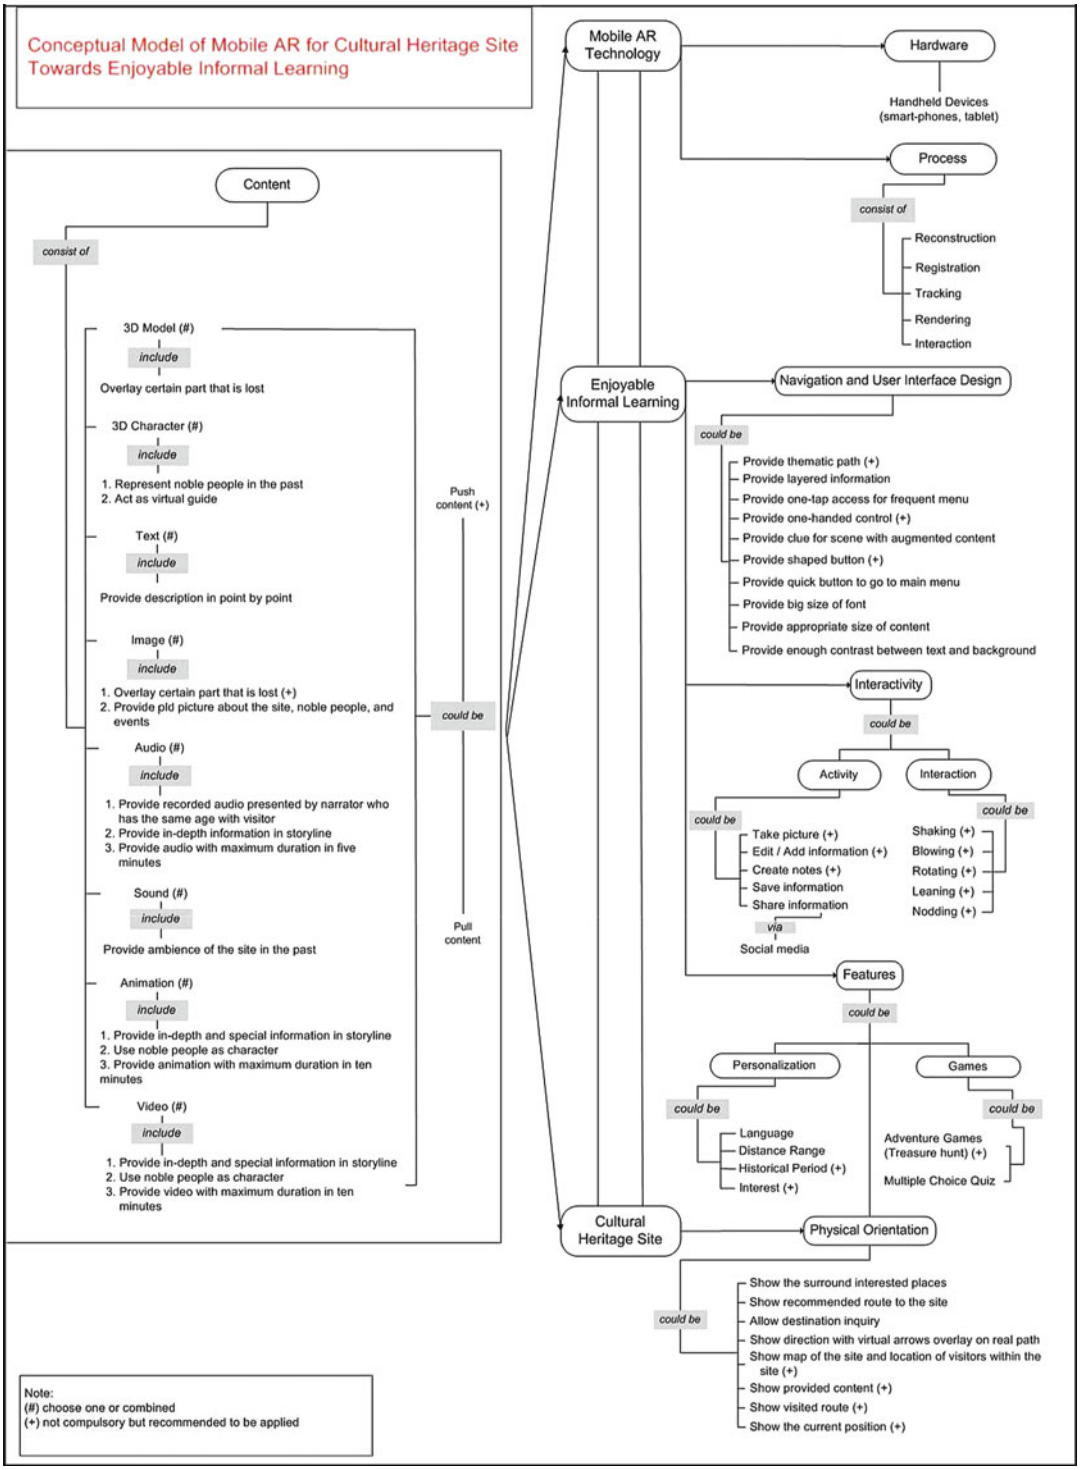
The Proposed Conceptual Model of Mobile AR for Cultural Heritage Site Toward Enjoyable Informal Learning

After all the validation process, the conceptual model was comprised to be finalized. There were six components and twenty-nine elements that is included in the conceptual model based on the validation (refer to Fig. 2). The explanation about component and element of conceptual model is provided in Table 5.

The conceptual model focuses on enjoyable informal learning. However, it integrates existing three main fields: mobile AR, enjoyable informal learning, and cultural heritage site (refer to Fig. 2). This becomes the uniqueness of conceptual model that is not implemented in the existing conceptual model. The proposed conceptual model is displayed.

Conclusion and Discussion

This study has produced a conceptual model of mobile AR for cultural heritage site towards enjoyable informal learning. The model comprises three structures, six components and twenty nine elements. The structures represent the main topic of conceptual model, which are, mobile AR, enjoyable informal learning, and cultural heritage. The component presents the



Conceptual Model of Mobile Augmented Reality for Cultural Heritage, Fig. 2 Revised conceptual model of mobile AR for cultural heritage site toward enjoyable informal learning

main component that are appropriate for conducting enjoyable informal learning at cultural heritage site, which are, content, navigation and user interface design, interactivity, features, hardware, and process. Lastly, the elements of content component are the backbone in realizing enjoyable informal learning.

The conceptual model aims to help developer in developing mobile AR for cultural heritage site toward enjoyable informal learning. It can be implemented to any platform, to a whole domain (mobile AR for cultural heritage site toward enjoyable informal learning), and to each domain (mobile AR, enjoyable informal learning, and cultural heritage site). Furthermore the conceptual model is also hoped to be used and to make a lasting impact onto the existence of cultural heritage site.

Constrained Edges and Delaunay Triangulation

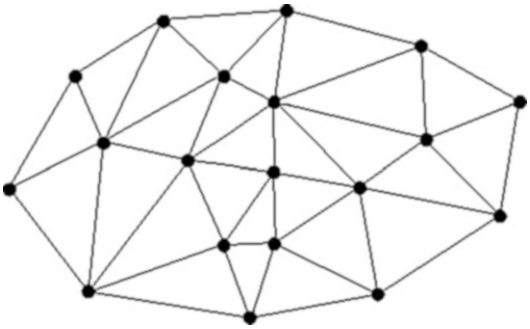
Simena Dinas[1] and Héctor J. Martínez[2]
[1]Facultad de Ingeniería, Universidad Santiago de Cali, Cali, Colombia
[2]Universidad del Valle, Cali, Colombia

Synonyms

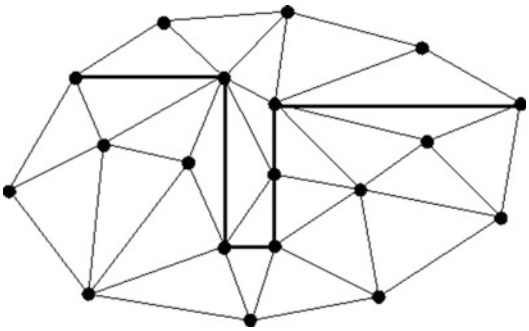
Delaunay tessellations; Delaunay Triangulation; *Delone tessellations*

Definition

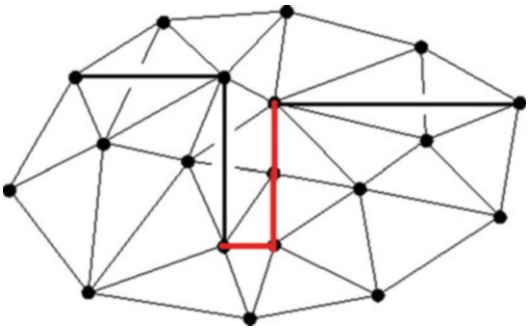
A Delaunay Triangulation is a triangle net in which every triangle satisfies the Delaunay condition: the circumcircle of each triangle includes only the vertices of the triangle. In other words, the circumcircle does not contain any vertex of other triangles (van Kreveld 2014). Constrained edges in a Delaunay Triangulation have been used as fixed edges into the triangulation. Constrained Delaunay Triangulation (CDT) and Delaunay Constrained Triangulation (DCT) are extensions of Delaunay Triangulation including constraints widely studied. The Fig. 1 represents a Delaunay Triangulation and the Figs. 2 and 3 depicts a CDT and a DCT, respectively.



Constrained Edges and Delaunay Triangulation, Fig. 1 Delaunay Triangulation



Constrained Edges and Delaunay Triangulation, Fig. 2 Constrained Delaunay Triangulation



Constrained Edges and Delaunay Triangulation, Fig. 3 Delaunay Constrained Triangulation

Introduction

An algorithm with optimal time to compute CDT was firstly proposed by Chew (1987), whereas Rognant et al. (1999) defined for the process of inserting constraints into a Delaunay Triangulation two different methods: stable and unstable. Stable methods begin with a Delaunay Triangulation, inserts a constrained edge, and produces another Delaunay Triangulation. Contrarily, an unstable method does not produce a Delaunay

Triangulation, for instance, CDT is an unstable method. Some CDT algorithms were documented by Agarwal et al. (2005); Shewchuk and Brown (2015).

Constrained Delaunay Triangulation

Given a set of n_1 vertices $V(n_1)$ and a set of m constrained edges $E(m)$, whose endpoints are $V(n_2)$, a CDT is a net of nonoverlapping triangles whose set of vertices is $V(n) = V(n_1)\ U\ V(n_2)$, all constrained edges $E(m)$ are included as edges of the triangulation and it is as Delaunay as possible. ($V(n_1)$ may be Ø.) The strong lines in the Fig. 2 represent the constrained edges.

Delaunay Constrained Triangulation

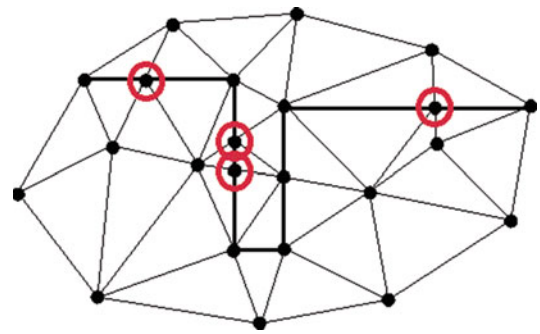
Given a set of n_1 vertices $V(n_1)$ and a set of m constrained edges $E(m)$, whose endpoints are $V(n_2)$, a DCT is a net of nonoverlapping triangles whose set of vertices is $V(n) = V(n_1)\ U\ V(n_2)\ U\ V(n_3)$, where $V(n_3)$ is a set of n_3 virtual vertices, all constrained edges $E(m)$ are included as edges of the triangulation, and it is a Delaunay Triangulation. ($V(n_1)$ and $V(n_3)$ may be empty.) Only the strong red lines are included in a DCT as constrained edges, then the strong black lines are ignored.

Delaunay Triangulation can use fixed edges, which are usually called constrained edges or briefly constraints. Delaunay Triangulation must be called CDT (for more details, see Chew (1987); van Kreveld (2014)). In a CDT, the priority is the constrained edges; it means, the triangulation must include the constrained edges. In other words, the most important is preserve constrained edges rather than the Delaunay structure. Consequently, the result is a triangulation including all the constrained edges even though some triangles do not pass the Delaunay condition (Chew 1987). In contrast, for DCT the most important is to conserve the Delaunay nature rather than guarantee the constrained edges (Rognant et al. 1999; Dinas and Bañón 2012). Thus, the result is a Delaunay Triangulation with as many as possible constrained edges (some constrained edges can be ignored or excluded of the final triangulation). However, there are a several ways to preserve the constrained edges and the Delaunay structure, but it requires virtual vertices. In the Fig. 4, the virtual vertices are enclosed in red circles.

Constrained Delaunay Triangulation

CDT were introduced independently as Generalized Delaunay Triangulation (Lee and Lin 1986) and as Obstacle Triangulation by Chew (1987). Restricted Delaunay Triangulation was the name used for others (Anglada 1997). A triangle is Constrained Delaunay if its interior does not intersect any input segment, and its circumcircle does not enclose vertices visible from the interior of the triangle. Nevertheless, an edge is Constrained Delaunay if it does not cross any input segment, and it has a circumcircle which does not enclose vertices visible from the interior of the edge.

Several authors have worked on CDT; for instance, Agarwal et al. (2005) worked on the efficiency for input-output data based on the construction process to optimize the use of the memory. Shewchuk (2008) explored the weighted Constrained Delaunay Tetrahedralizations whereas Dinas and Bañón (2012) proposed to take data from images; the construction of Delaunay Triangulation uses a cloud of points from images and a set of edges E captured from images are the constrained edges for Constrained Delaunay Triangulations. Dinas and Martínez (2019) worked on the constrained edges and Kinetic Delaunay Triangulation as a collision detection approach. In contrast, Domiter and Zalik (2008) worked on accelerating the location process for inserting new vertices, whereas Nam et al. (2009) worked on accelerating the algorithm and Eder et al. (2018) worked on the parallelization of the polygons with holes in



Constrained Edges and Delaunay Triangulation, Fig. 4 Delaunay Constrained Triangulation and virtual vertices

Constrained Delaunay. Additionally, refinement methods have been used to improve CDT Algorithms (Engwirda and Ivers 2015).

Constrained Delaunay Triangulation Algorithms (CDT)

The input is a set of constrained edges usually called a Planar Straight-Line Graph (PSLG) and the set of vertices of the triangulation. The output is a CDT where every edge is locally Delaunay except for constrained edges.

Incremental Construction

Anglada's algorithm (Anglada 1997) starts with a Delaunay Triangulation that is constructed using the set of vertices $V(n)$, and then localizes the constrained edge in the triangulation.

Incremental Insertion

Based on Anglada's algorithm (Anglada 1997), the proposal of Nam et al. (2009) accelerates the point location by using Skvortsov's algorithm and a uniform grid.

Randomized Incremental Construction

A randomized implementation based on Anglada's algorithm (Anglada 1997) was proposed by Agarwal et al. (2005). This approach includes in the Delaunay Triangulation the endpoints of the constrained edges, it means, the endpoints of the constrained edges are used to construct the Delaunay Triangulation.

Randomized Incremental Segment Insertions

Typical implementations for segment insertion take $O(kn^2)$, where n is the number of input vertices and k is the number of input segments. Inserting a constrained edge into a CDT takes $O(n \log n + n \log^2 k)$ (Agarwal et al. 2005). This algorithm deletes the edges intercepted by the constrained edge, inserts the constrained edge in the cavity, and retriangulates it. An improved algorithm proposed by Shewchuk and Brown (2015) decreases the complexity to $O(n \log^2 k)$ by computing the segment location procedure before the segment insertion procedure. Finally, the Shewchuk and Brown (2015) is close related to the Chew's implementation of deleting a vertex in linear time.

Divide and Conquer

Chew (1987) proposed a divide and conquer algorithm for CDT. The set of vertices $V(n)$ is divided into vertical rectangles, which contains exactly one vertex. Additionally, there are crossing lines inside the rectangle that represent the constrained edges. Thus, the triangulation is constructed by using the crossing lines and the constrained edges. Finally, the strips are merged to complete the CDT; it takes $O(n \log n)$ time (Chew 1987).

Plane Sweep

Domiter and Zalik (2008) proposed an algorithm focused on the main bottleneck of the algorithm: locating the triangle in which a new vertex falls; thus, the cost of inserting an edge into a CDT decreases. The worst time complexity of the proposed algorithm was $O(n^2)$.

Delaunay Constrained Triangulation (DCT)

DCT produces stable method because the final triangulation guarantees the Delaunay structure and respects constrained edges, at the same time. Stable methods can be constructed by inserting new vertices in the triangulation referred as Virtual Vertices. It is also known as Conforming Delaunay Triangulation; its edges are all locally Delaunay. As DCT is a Delaunay Triangulation, the construction time is related to the Delaunay time, but the number of virtual vertices depends on the selected method. Additionally, Shewchuk (2008) reported Conforming Delaunay Triangulation. The proposed algorithms accept in the input small angles, and then new vertices are included to increase the quality by eliminating small angles. In the worst case, the input needs!(n^2) to $O(n^{2.5})$.

Rognant et al. (1999) defined stable and unstable methods according to the result: they are stable if they produce a Delaunay Triangulation.

Virtual Vertices

A virtual vertex is a vertex, which does not belong to the initial set of vertices $V(n)$ of the triangulation; it is created to divide constrained edges into smaller pieces with the purpose of creating a DCT. Several authors have been working on inserting vertices to the triangulations by different methods; for instance, the Steiner Points by Engwirda and Ivers (2015). Virtual vertices use the constrained edges; nevertheless, its creation or selection depends on the applications. For instance, virtual vertices can be created by the intersection between a pair of constrained edges or between a constrained edge and a Delaunay edge. According to the kind of intersection, it can be classified into three groups: (i) An X intersection, it is necessary to divide two constrained edges into four new constrained edges, where each constrained edge has a unique vertex and one virtual vertex. (ii) A T intersection, it happens when an endpoint of a constrained edge is involved in the intersection. It requires to split only one edge into two edges, but it is not required to create a new virtual vertex, and (iii) an L intersection, which does not require virtual vertices.

Delaunay Constrained Triangulation Methods

In this section, the set of methods that can be used to construct a DCT is explained.

Constrained Delaunay Triangulation

CDT respects constrained edges, and the resulting triangulation is as close as possible to a Delaunay Triangulation; it means, there is not guaranteed that the resulting triangulation is a Delaunay Triangulation. An advantage of this triangulation is that their construction does not require additional vertices and the disadvantage of this triangulation is that it is not always a Delaunay Triangulation. To guarantee both, the constrained edges and the Delaunay Triangulation, it is possible to convert a CDT into a DCT by inserting new vertices inside the triangulation. In the next sections are briefly documented the following methods: densification, dichotomy, orthogonal projection, intersection, bisection, and trisection methods.

Densification

Densification method is constructed by a set of steps that should be applied to each constrained edge inside the triangulation (see Fig. 5). The first step is to find in the set of vertices $V(n)$ the nearest vertex to the constrained edge. After, to calculate the length d from this vertex to the constrained edge; d is used to divide the constrained edge into m small constrained edges with length of at least d. That is to say, at least m – 1 of the m new small constraints have size d (Faugeras et al. 1990); however, it can be modified to include m segments with equal length. This method can produce a big number of virtual vertices; however, the main advantage of this method is that it does not require the inCircle test for the new the triangles.

Dichotomy

A DCT is created by dividing each constrained edge into small constrained edges; the size of each segment can be defined by the author or can be randomly selected, as is shown in Fig. 6. The densification method guarantees the existence of the right set of virtual vertices of the dichotomy method. Compared to the densification method, it

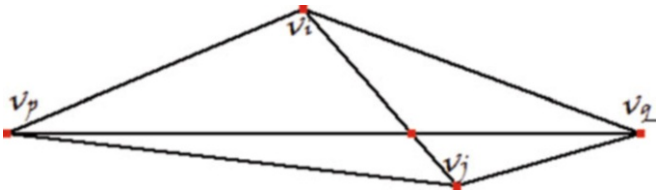
Constrained Edges and Delaunay Triangulation, Fig. 7 Orthogonal projection method for Delaunay Constrained Triangulation



Constrained Edges and Delaunay Triangulation, Fig. 8 Intersection method for Delaunay Constrained Triangulation

is equally reliable; it is computationally less expensive and requires less additional vertices. The advantage of this method is that it defines the constrained edge partition as simple as possible and it does not produce more virtual vertices than necessary for the triangulation to be Delaunay; the disadvantage is that it requires the inCircle test for the new triangles. Rognant et al. (1999) reported a brief explanation.

Orthogonal Projection

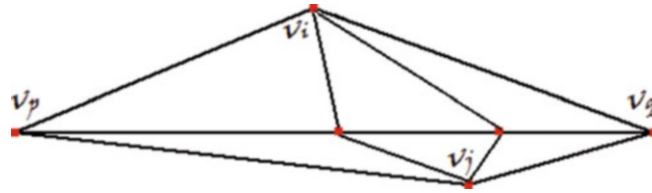
In Fig. 7, the orthogonal method is done for each vertex located around a constrained edge. Each of these vertices is orthogonally projected on the constrained edge; consequently, it produces an edge that is orthogonal to the constrained edge. Thus, each virtual vertex is the orthogonal projection of the vertex on the constrained edge. This method is reliable; the orthogonal projection is not a complex procedure; additionally, the number of new virtual vertices depends on the number of vertices that are around to the constrained edge (Rognant et al. 1999). The shortcoming of this method is that the cost of calculating the virtual vertices is computationally high.

Intersection

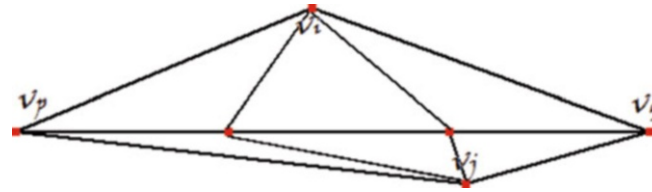
The result of overlapping a Delaunay Triangulation and be constrained edges is shown in Fig. 8; the intersection between the constrained edges create the virtual vertices. This method can be used to insert constrained edges into a Delaunay Triangulation. When the Delaunay Triangulation is unknown, constructing it can be more expensive than using another method; however, it is reliable. A fast way to create the intersection vertices is to find a pair of vertices on opposite sides that surround the constrained edge, and then calculate the intersection vertex between the constrained edge and the segment formed by the pairs of vertices surrounding the constrained edge. Finally, complete the triangulation by connecting the virtual vertices with the surrounding vertices (Rognant et al. 1999). This approach is based on the Anglada's algorithm to insert segments in a CDT (Anglada 1997).

Bisection

Bisection method is based on a divide and conquer approach depicted in Fig. 9: it is simple to implement, and the inCircle test must verify the result. The first step is to bisect the constrained edge and



Constrained Edges and Delaunay Triangulation, Fig. 9 Bisection method for Delaunay Constrained Triangulation



Constrained Edges and Delaunay Triangulation, Fig. 10 Trisection method for Delaunay Constrained Triangulation

locate a virtual vertex. Then connect the virtual vertex with the set of vertices surrounding the constrained edge. Finally, evaluate the triangles by the inCircle test, if any triangle does not satisfy the circumcircle condition, then bisect the piece of the constrained edge again until each triangle satisfies the circumcircle condition. The advantage of this method is that it defines a simple constrained edge partition and it does not produce more virtual vertices than necessary for the triangulation to be Delaunay. The shortcoming of this method is the necessity of evaluating the result after each division. Other methods as densification and intersection methods produce correct DCT and do not require evaluation; however, their procedure to locate the virtual vertices is not as straightforward as the used for bisection method.

Trisection

This method is based on a divide and conquer approach (see Fig. 10) it is simple to implement, and the inCircle test must verify the result. The first step is to trisect the constrained edge and locate two virtual vertices. Then connect the virtual vertices with the set of vertices surrounding the constrained edge. Finally, evaluate the triangles by the inCircle test, if any triangle does not satisfy the circumcircle condition, then trisect the piece of the constrained edge again until each triangle satisfies the circumcircle condition. The advantage of this method is that it defines a simple constrained edge partition and it does not produce more virtual vertices than necessary for the triangulation to be Delaunay. The shortcoming of this method is the necessity of evaluating the result after each division. Other methods as densification and intersection methods produce correct DCT and do not require evaluation; however, their procedure to locate the virtual vertices is not as straightforward as the used for bisection method. The number of virtual vertices produced by the bisection and trisection are expected to have similar behavior, even though the bisection method requires more levels of partition, but the trisection method produces more virtual vertices per partition.

Conclusion and Discussion

Delaunay Constrained Triangulation and Constrained Delaunay Triangulation have remarkable difference between them. Both triangulations can be used to represent constrained edges in a triangulation; however, the use depends on the purpose. While CDT is flexible with Delaunay Triangulation, it is much stricter with constrained edges. In contrast, DCT is flexible with constrained edges but stricter with a result that passes the conditions of Delaunay Triangulation. The inclusion of artificial vertices called virtual vertices can help to guarantee both: the Delaunay structure and de constrained edges. Finally, reviewed methods are based on virtual vertices: densification, orthogonal projection, dichotomy, and intersection, and the proposed methods: bisection and trisection.

Definition

Construction of game agents though simulated evolution is the use of algorithms that model the biological of process of evolution to develop the behavior and/or morphology of game agents.

Introduction

Computer game worlds are often inhabited by numerous artificial agents, which may be helpful, neutral, or hostile toward the player or players. Common approaches for defining the behavior of

such agents include rule-based scripts and finite state machines (Buckland 2005). However, agent behavior can also be generated automatically using evolutionary computation (EC; Eiben and Smith 2003). EC is a machine-learning technique that can be applied to sequential decision-making problems with large and partially observable state spaces, like video games.

EC can create individual agents or teams, and these agents can be opponents or companions of human players. Agents can also be evolved to play games as a human would, in order to test the efficacy of EC techniques. EC can even create game artifacts besides agents, such as weapons. The reason EC is so flexible is that it requires little domain knowledge compared to traditional approaches. It is also capable of discovering surprising and effective behavior that a human expert would not think to program. If applied intelligently, this approach can even adapt to humans in a manner that keeps providing interesting and novel experiences for players. This article focuses mostly on discovering effective opponent behavior (since that is the focus of most research), although examples of other applications are also given when appropriate.

Evolutionary Computation

EC models the process of Darwinian evolution by natural selection (Darwin 1859) for the purpose of generating solutions to difficult embedded problems. Initially, a random collection of candidate solutions, called the population, is generated and evaluated in a task within some environment. Because of randomness in how the population was generated, there will be variation in the performance of different candidate solutions. At this point a new population is generated from the old population using a mixture of selection, recombination, and mutation.

Selection is based on Darwin's concept of natural selection, by which fitter individuals enjoy higher reproductive success. It involves identifying members of the population that perform best, typically through a fitness function that maps candidate solutions to numeric measures of performance. Sometimes a certain number of top performers are selected directly (a technique known as elitism), but selection is generally a random process that merely favors high-performing individuals, while still allowing some poor-performing, but lucky, individuals to be chosen. This random element is one way of maintaining diversity in the evolving population and is generally important to the long-term success of evolution.

In order for evolution to progress, some of the slots in the new population must be filled by results of recombination or mutation. Recombination creates a new solution to the problem by combining components of solutions that were selected from the old population. Generally, two solutions from the old population, called parents, are selected and recombined to create a new solution, a child or offspring, via simulated crossover, which models the process of genetic crossover that is a major benefit in biological sexual reproduction. In addition, some of these offspring undergo mutation before joining the new population.

Mutation operations are applied with low probability and generally result in small changes to a candidate solution. It is also possible, and common, for mutation to be applied directly to members of the old population to generate new solutions, which can also fill slots in the new population. Mutation without recombination models asexual reproduction.

The new population of candidate solutions is labelled the next generation of the evolutionary process. The new population now also undergoes evaluation and is subject to selection, recombination, and mutation, which leads to yet another generation, and so on. Because recombination and mutation keep creating new individuals, this process is able to search the space of possible solutions in parallel, and because selection favors high-performing individuals, this search will gradually focus on the best solutions in the search space. As such, the evolutionary process is repeated until some stopping criteria is reached, such as the attainment of a desired level of performance, or the end of a preset number of generations.

A major benefit of this process is that it is general: it can be applied to any domain in which there is a measure of fitness/performance that allows certain solutions to be identified as being better than others.

Evolution in Games

Games are typically full of numeric scores and metrics that can easily be used as a means of measuring agent performance. Each possible agent is a candidate solution to the problem of how to behave in the game world. Several different representations for such agents are discussed later, but even given such a representation, there are different ways of evaluating an agent's performance.

Although most game agents are ultimately designed to interact with humans, having humans evaluate all candidate solutions is seldom feasible because it is difficult for humans to maintain focus and evaluate solutions consistently. Completely automated approaches are more commonly used, but sometimes humans can also be incorporated into the process.

Evolution in Stationary Worlds

A simple approach to evolving agent behavior is to have an evolved agent interact only with a static or stationary world. Such worlds may have no other agents in them or may only have agents with fixed control policies. A world is stationary if it and its agents do not adjust or adapt to what occurs during evaluation. In other words, the probability of experiencing certain outcomes in certain situations remains the same.

An example of an agent evolving in a stationary world without other agents is a racecar controller on a track without other cars. This process can produce skilled racing behavior (Cardamone et al. 2009). To add to this agent the ability to interact with other racecars, a scripted component could be added to the controller that takes over when other cars are near, thus combining scripted and evolved components. Another option is to evolve a racecar controller in an environment filled with scripted opponent cars. A variety of different scripted opponents could be used, either in one trial or across the course of several, in order to make the discovered behavior more robust in the face of different opponents.

Scripted controllers could be rudimentary yet still pose an interesting challenge for an evolved controller to overcome. However, scripted opponents may have weaknesses that evolution can discover and exploit. Such behaviors may result in a high score, even though they may be uninteresting or easily defeatable for human players. Fortunately, the evolutionary approach can be generalized and extended into a process that discovers good behaviors in an absolute sense. This process is coevolution.

Coevolution

Coevolution occurs when individuals in a population are evaluated with respect to other evolved individuals. Such individuals can come from the same or different populations and can be evaluated in tasks requiring cooperation or competition. A prominent example of competitive coevolution within a single population is Fogel's (2002) evolved checkers player, Blondie24. Blondie24 was evolved by an evolutionary algorithm that pitted evolved players from a single population against each other. The players that did a better job of defeating other members of the same population had higher fitness and were used to create more offspring for the next generation. The best individual after many generations used the name Blondie24 on an online checkers service and was found to be highly competitive against the human players it faced.

Although checkers is a traditional board game, the same coevolutionary process can be used in video games where bots are needed to fill in for human players. First-person shooter (FPS) games, like the Unreal Tournament and Quake franchises, fit this model because during the deathmatch mode of play (a free-for-all competition between agents trying to kill each other for points), all agents in the game have the same in-game representation and available action set, making it straightforward to evolve such agents with a single homogeneous population.

When the representations and available actions of different classes of agents are different from each other, it makes more sense to evolve separate populations for each type of agent and define their fitnesses in relation to each other. For example, fighting games, like the Street Fighter and Tekken franchises, pit two characters against each other in direct one-on-one competition and generally feature a variety of characters. Therefore, the abilities of the two players may be completely different from each other.

For example, assume that the goal of coevolution is to discover skilled controllers for Ryu and Guile in Street Fighter (at least, each controller will become skilled with respect to its particular opponent). In this scenario, there is a population of Ryu controllers and a population of Guile controllers: each evaluation is a match between a member of each population in which performance depends on the amounts of damage dealt and received by each controller (there are various ways to evaluate performance with respect to these two scores). Any improvement in the performance of individual Ryu controllers will come at the expense of Guile controllers, because the two populations are in direct competition. When set up correctly, this process will result in an evolutionary arms race, encouraging each population to find new ways to overcome the other.

However, there are many potential pitfalls to this process. For example, because each member of each population is different, evaluations of the Ryu population will not be consistent if each Ryu controller faces a different member of the Guile population. There is a risk of a mediocre Ryu controller receiving a high performance rating simply because it was paired with a poor Guile controller. This problem can be somewhat mitigated if every member of each population faces off against several members of the other population, and overall performance depends on performance in all evaluations. However, performance will only be completely consistent if the set of opponents for each population is the same, and picking an appropriate set of opponents is challenging.

Unfortunately, if the set of opponents is chosen poorly, the two populations will not improve in an absolute sense. Instead, they may simply get better with respect to each other in ways that a human player will find bizarre or incompetent. Such improvements may go through alternating cycles because they lead to behavior that beats the current prevalent opponent behavior but has a weakness against another easily discovered opponent behavior. The trick with coevolution is to discover behavior that incorporates all of the strengths while avoiding all of the weaknesses available within the population's range of possible behaviors.

In some domains, performance that is good in an absolute sense will be achieved automatically. In others, it may be necessary to keep evaluating each population against an archive of defeated opponents to assure that agents never lose the ability to overcome opponents their ancestors could defeat.

Although coevolution can give rise to behavior that is intelligent in an absolute sense, it is hard to implement correctly. However, agent behavior only needs to be interesting with respect to human players, and there are also ways to evolve agent behavior by including humans in the loop.

Evolving with Humans in the Loop

As mentioned before, the main challenges to evolving against humans are that they have a limited ability to maintain focus for long periods of time and that they are not consistent in their evaluations.

A computer can usually run many evaluations between computer opponents very quickly, but all evaluations with a human must occur in real time. After many such evaluations, a human is likely to become fatigued and be unwilling to expend the necessary effort to evaluate agents properly. Naturally, this tendency also makes evaluations inconsistent. However, fatigue is less likely to occur if it is possible to evaluate many agents at once, or if the population is sufficiently small. Fatigue can also be avoided if a prolonged evaluation process is simply the point of the game.

For example, the commercial Creatures (Grand et al. 1997) series of games is centered around raising artificial creatures called Norns. Superficially, the game looks like a virtual pet-style

game, but among many other AI techniques applied in the game is support for evolution. The creatures the player raises grow, mature, and seek mates. The Creatures games take place in open-ended worlds in which the fun comes from nurturing and interacting with Norns. However, these lengthy interactions influence when and with whom each Norn mates and therefore influence the direction evolution takes in the creation of new Norns.

The model used in the Creatures games is interesting and unique, but too slow and time intensive to be useful in most other genres. Inconsistency in human evaluations is also not terribly relevant in the Creatures games because variation and novelty in the results of evolution are part of the fun of the game. Additionally, there is no set goal that the evolved Norns are supposed to achieve, but the game is entertaining precisely because of the variety it produces.

Another manner in which a human may be an inconsistent evaluator is due to a human's tendency to learn and adapt: a human player that changes strategy mid-generation will evaluate members of the same generation differently, which would likely give an advantage to agents evaluated before the human adopted a new strategy.

However, human adaptation is also a potential benefit. Inconsistent evaluations may add noise to the evolutionary process, but in the long run a human or set of humans who evaluate artificial agents will settle on strategies that suit their computer opponents. However, if the humans adapt and improve, then the evolved agents should improve as well. In fact, if this improvement happens in real time, then the resulting experience is more exciting and engaging for the human player.

Therefore, the primary challenge to evolving agents with humans in the loop is in generating new and interesting behaviors quickly enough to keep humans engaged. In general, having one human be responsible for evaluating all individuals puts an unreasonable burden on that individual, so methods that keep humans in the loop need to distribute evaluations in novel ways. These evaluations can either be distributed among several different humans or split between humans and the computer.

Sharing evaluations with the computer means that the computer still evaluates the majority of candidate solutions in the usual way, using a computer-controlled opponent as a stand-in for a human player. This process could in fact be carried out for many generations, only occasionally letting a human face the best evolved agents. If performance against the human is comparable to performance against the computer-controlled stand-in, then evolution is on the right track. Otherwise, data on how the human plays can be collected and used to adjust the behavior of the stand-in. These adjustments can be made using supervised learning techniques, or by evolving the stand-in to emulate human play better. However, such a system is complex, and a great deal of effort is required to make sure all of the separate components successfully interact.

A conceptually simpler way to distribute evaluations is across many human players. Although using different human players makes inconsistencies in evaluation even more likely, there will at least not be any systematic tendency toward generating behaviors that are inappropriate for human consumption: if any human can exploit an agent's failings, then it will eventually be weeded out of the population. Furthermore, distributing evaluations across many humans is made easier by the Internet: specifically, tools such as Amazon's Mechanical Turk and massively multiplayer online (MMO) games.

In fact, although the MMO model has not yet been used to evolve agent behaviors specifically, EC has succeeded in the MMO video game Galactic Arms Race (Hastings et al. 2009). This space-based action shooter game evolves diverse weapons for users to find and equip on their spaceships. The weapon preferences of all users determine the fitness of weapons. The most popular weapons are more likely to create offspring, i.e., new weapons that players are given when they defeat certain enemies. A similar model could apply for enemy agents in many MMO worlds, with enemies that are more successful in combat with human players being considered more fit,

and giving rise to increasingly challenging offspring. Such a process has the potential to give rise to new types of games in which all agents evolve and adapt based on a community of human players.

Evolving Humanlike Behavior

Pitting evolved agents against human opponents will assure that incompetent behaviors are weeded out of the population. However, simply discovering skilled behavior is not always a problem. Because artificial agents are differently embodied than human-controlled avatars, they may have unfair access to skills that are difficult for humans to develop, which in some cases means that they quickly become too skilled to be good opponents for humans. For example, in Unreal Tournament 2004, artificial agents can be programmed using a system called Pogamut (Gemrot et al. 2009). It is easy for these agents to shoot their weapons with pinpoint accuracy: evolution thus creates skilled agents, albeit in a way that human players find frustrating and inhuman.

However, evolution can still be applied in these situations. Agents can be evolved to maximize performance, but under restrictions similar to those experienced by humans. The ability of such an agent to behave in a humanlike manner was demonstrated in the 2007–2012 BotPrize competition. The purpose of the competition was to develop bots for Unreal Tournament 2004 that human players would mistake for humans at least 50 % of the time. The bot UT^2 achieved this goal with evolved combat behavior (Schrum et al. 2012). The key idea was to optimize the behavior under humanlike restrictions: the more quickly it was moving and the farther its targets were, the less accurate it was. These restrictions forced the bot to evolve humanlike movement patterns in order to have skilled behavior.

This example demonstrates how the abilities available to an evolved agent have a strong influence on the range of behaviors that are likely to be evolved. These abilities are in turn influenced by the type of controller evolved for the agent. A variety of controllers that can be evolved to produce game agents are discussed next.

Evolved Representations

When constructing agents for games via evolution, each candidate solution is a means of representing an agent. Often, this representation needs only account for the behavior of the agent, because its form is often fixed by the constraints of the game. However, diverse agent morphology can also be evolved. Regardless, there are a variety of representations that can be used to suit the needs of any particular game.

Parameter Tuning

The simplest way to incorporate evolution into traditional agent design is via parameter tuning. If there is an existing controller for an agent whose behavior is influenced by some key parameters, then these parameters can be optimized using evolution (typically via genetic algorithms or evolution strategies).

For example, a hand-coded controller for an agent in an FPS may have numeric parameters indicating which weapon to favor, depending on the agent's distance from its opponents. Similarly, such an agent may have several distinct control modules, like *attack*, *retreat*, and *explore*, and might decide which one to use based on numeric features such as its own health and its distance from enemies and items. Evolved parameters then specify the exact thresholds for each feature, indicating when one module is used instead of another.

The strength of parameter tuning depends on the strength of the underlying controller. For a bad controller, no amount of parameter tuning may be able to help. Similarly, a very good controller may not be very difficult to tune, resulting in quick but small improvements in performance. In order for evolution to reach its full potential, the evolved representation needs to exist within a search space that is rich enough to contain skilled solutions that a human designer either would not consider, or would have difficulty creating.

Rule-Based Scripts

Rule-based scripts are a common approach to specifying the behaviors of agents in commercial games. Typically, considerable effort and person-

hours go into designing scripts for each agent in the game. Simple agents can have simple scripts, but scripts for opponents must be complicated in order for the game to be challenging and interesting.

Scripts generally consist of a list of rules, and each rule consists of a trigger and a corresponding action or sequence of actions. Triggers and actions may also be parameterized. Evolution can easily rearrange blocks of information and search the parameter spaces of each rule and trigger. Of course, the process can be difficult if there is a large number of basic triggers and actions.

One game genre in which opponents have a large range of possible actions is real-time strategy (RTS) games. Because the computer opponent must control a collection of agents in a large space, the number of actions available is massive. Therefore, it makes more sense to reason about behavior at a higher level. Given a set of high-level actions, or tactics, to choose from, a reinforcement learning technique called dynamic scripting can be used to select the best tactic for each situation, leading to improved behavior. In its basic form, this technique is still limited by the preprogrammed tactics available to the agent. However, dynamic scripting can be combined with evolution that generates new tactics. This process has been successfully applied to Wargus, a clone of the very popular Warcraft II RTS game (Ponsen et al. 2006).

Since commercial game designers are already comfortable using scripts, evolving scripts is a straightforward way to combine existing industry knowledge with cutting-edge AI techniques. However, there are also evolvable representations that are potentially more powerful, but less well known in the game industry.

Genetic Programming

Genetic programming (GP) is a technique for evolving computer programs, or more accurately subroutines, that are often represented as trees. Each internal node is a function call whose branches are input parameters, and leaves are either constants, or functions with no parameters. These functions with no parameters provide sensor values from the agent to the program.

For any given game, the specific functions that can be used in evolved trees need to be specified by the programmer. The types of functions used depend on how the evolved trees are used to control an agent. Evolved trees could be straightforward function approximators made up of purely mathematical functions using agent sensors to provide numbers. However, trees with arbitrarily complex functions can also be evolved. For example, functions can have side effects that directly lead to agent action or that alter a stored memory structure whose contents can influence future function evaluations.

GP can also be used to evolve behavior trees. Such trees hierarchically decompose behavior into a collection of tasks that are prioritized and then executed only if certain triggers are satisfied. In fact, a behavior tree can be thought of as a hierarchical rule-based script. Behavior trees were initially developed for the commercial release of Halo 2 (Isla 2005) and have since been evolved in Unreal Tournament 2004 using Pogamut (Kadlec 2008).

GP can also be used as part of a developmental process: the evolved programs are executed to create some other structure that is actually used to control the agent. Such a process more closely emulates the creation of complex organisms from DNA. With GP, an evolved program tree can be used to create the structure and weights of a neural network (Gruau et al. 1996) or simply be queried to fill in the weights of a predefined network architecture (Togelius et al. 2009). Neural networks have their own set of advantages as agent control mechanisms, which are discussed next.

Neuroevolution

The human brain is a neural network made up of neurons that connect to each other via synapses and communicate via electrical signals. An artificial neural network is an abstraction of this idea that transmits numerical values in place of electrical signals, and neuroevolution is the process by which artificial neural networks are evolved to solve problems.

There are many neural network models (Haykin 1999), but the most common is a multilayer perceptron (MLP), consisting of input

neurons, output neurons, and hidden neurons in between. Each neuron is connected to every neuron in the next layer, and a continuous activation function, typically a sigmoid, transforms the numerical signals accumulated in each neuron. MLPs are universal function approximators, assuming the correct number of neurons/layers is available, so they are useful in defining agent behavior. MLPs can be trained by supervised learning if labelled training data is available, but this is seldom the case when defining agent behavior in games.

MLPs typically have their architecture (number of neurons in each layer) fixed before learning, and in such a setting there is a known number of synaptic weights in the network. Discovering the weights for such networks is therefore a special case of parameter tuning. Although intelligent behavior can be learned using MLPs, the large number of parameters can make it difficult to learn particularly large MLPs.

An alternative approach is NeuroEvolution of Augmenting Topologies (NEAT; Stanley and Miikkulainen 2002), which does not produce MLPs. Rather, NEAT networks can have neurons connected to each other in an arbitrary topology. All networks start evolution with a minimal topology with no hidden neurons. The networks in the population gradually complexify across generations as new neurons and links are added via mutations, which allows for convoluted, but effective topologies. In fact, by beginning the search in a small space with few links, it is often possible to find very effective simple networks with fewer links than an MLP with the same number of inputs and outputs.

A variant of NEAT that allows a team of agents to learn in real time (rtNEAT; Stanley et al. 2005) was actually the driving force behind a machine-learning game called Neuro-Evolving Robotic Operatives (NERO), in which the player takes on the role of a virtual drill sergeant to train robot soldiers that learn via neuroevolution. NEAT has since then been applied to many other video games.

An extension to NEAT called HyperNEAT (Stanley et al. 2009) can exploit the geometry of a state space to make learning certain behaviors easier. HyperNEAT networks are evolved with NEAT, but with extra activation functions possible in the neurons to capture symmetries and repeated patterns in the domain. Most importantly, each evolved network is used to create another network, which becomes the actual controller of an agent. This is another example of a developmental process (cf. section "Genetic Programming"). A benefit of this process is that it becomes feasible to generate very large, but effective, controller networks from small evolved networks. In fact, HyperNEAT has been effectively applied to simulated RoboCup Soccer Keepaway (Verbancsics and Stanley 2010) and general game playing of Atari games (Hausknecht et al. 2012) using controller networks whose input layers were linked to 2D grids spanning the entire visual display. Such massive networks are difficult to evolve when each connection weight must be learned individually.

HyperNEAT is known to produce regular networks with repeating patterns. However, these networks are not inherently modular (though techniques to encourage such modularity exist; Huizinga et al. 2014). Modularity is useful because a challenging problem can be broken down into smaller components that are easier to learn. Breaking up a controller into several distinct subcontrollers is a useful way to achieve multimodal behavior, i.e., behavior that consists of distinct modes subjectively different from each other. Such behavior is necessary in many games, because different strategies often require different actions, such as attacking, retreating, searching, hiding, etc.

Such multimodal behavior can be discovered with neuroevolution through architectures that support multiple distinct output modules. Such modules can exist in the initial population or be added by a mutation operator called module mutation (Schrum and Miikkulainen 2014). This technique was applied to Ms. Pac-Man, and the evolved networks discovered both expected modes of behavior – such as a mode for fleeing threat ghosts and a mode for chasing edible ghosts – and unexpected modes of behavior, such as one for dodging ghosts after luring them

near a power pill, so that when the ghosts became edible they would be easier to eat.

So far, only means of evolving complex controllers have been discussed. However, it is possible to go beyond evolving controllers and evolve the bodies of agents as well.

Morphology

EC can be used to create many types of structures beside function approximators. The Evolved Virtual Creatures (EVCs; Sims 1994; Lessin et al. 2014) community has developed ways of evolving interesting creature morphologies, often using graph-based encodings. These encodings allow for arbitrary numbers of limbs and joints arranged in novel ways. Sometimes these morphologies mimic those of real-world organisms, but more unusual morphologies can also emerge; the strange quality of such morphologies would lend itself well to a game filled with aliens, robots, or other bizarre creatures.

Given the body, a means of controlling it is required. Specifically, engaging and disengaging the existing joints and/or artificial muscles will cause parts of the body to move, which can lead to complex behavior if done properly. Sometimes simple repetitive control signals, as from a sine wave, can lead to interesting behavior given the right morphology. Naturally, a human designer could also step in and provide the behavior for an evolved morphology.

However, EVCs can also have their control routines embedded into their morphologies. In particular, specific sensors situated on an EVC can be linked to its muscles and joints. Internally, these connections can be wired in a manner similar to a neural network or electrical circuit, meaning that sensor values may be aggregated and/or serve as inputs to functions, whose outputs are passed on until they eventually determine muscle and joint behavior. Such controllers have been evolved to run, jump, swim, grab objects, chase after a light source, and fight or flee different opponents. These skills could serve as the building blocks for more complex and interesting game agents.

Conclusion

Evolutionary computation is a powerful machine-learning technique that has been used to discover skilled and interesting agent behavior in many domains. Video game agents can be evolved to play the game as a human would, to serve as opponents for human players, or can be evolved in a context where interacting with the evolutionary process is the point of the game.

Despite the ability of evolution to discover diverse and interesting agent behaviors, the commercial games industry has not yet harnessed the power of evolution (and other advanced AI techniques). This article provides a useful starting point for understanding what can be done with evolution in games and also points out some areas of untapped potential.

Synonyms

Building information modelling of construction; Building product modelling

Definition

The modelling of construction process can be defined as a procedure of collecting tangible and intangible data that is needed for a successful operationalization of construction activities. For decades, construction process modelling has largely remained manual and or partially information technology centric. This article discusses the use of digital information modelling tools as a medium for modelling construction processes as a way of improving performance in the built environment.

Introduction

The worldwide realization of the potential benefits associated with the deployment of building information modelling (BIM) (Jamil and Fathi 2018) has created, inter alia, a destructive force of unrealistic framing and hype (Fox 2014) attributable to

stifling process modelling of construction activities. On one hand scholars claim that BIM has proven and outstanding results in construction processes by enhancing knowledge sharing with regard to a building or facility throughout its life cycle from the conceptual design to facility management (Jamil and Fathi 2018; Khosrowshahi and Arayici 2012; Aranda-Mena et al. 2009; Lindkvist 2015). On the other hand, scholars believe that as innovative as BIM strategies could be (Murphy 2014), the construction industry still requires a massive effort with regard to modelling information related to processes pertinent to delivery of projects (Fox 2014; Motawa and Almarshad 2015; Bosch et al. 2015). Currently the construction industry uses pervasive data modelling tools such as digital cameras, tablet computers and other handheld gadgets, drones, and the like (Aziz et al. 2017) to capture data on building product and processes. This implies that the industry uses varied digital gadgets to capture and generate data of varied sort at any stage in the construction process; hence, the industry remains largely fragmented in the way it handles construction data (The Infrastructure and Projects Authority 2016). While the technology to capture building product data is fully developed, there is a challenge related to modelling tacit knowledge from a section of experienced construction management workforce. The introduction of the BIM strategy of construction delivery, as is the case with Level 2 BIM initiative of the UK government of 2016 (The Infrastructure and Projects Authority 2016), essentially takes away the most familiar and user-friendly means of modelling knowledge and ideas (paper, pen, and the like) on construction processes. The unintended consequences of using BIM have been the massive loss of knowledge because current technological systems are ill-prepared to capture data from highly experienced workers who are disinterest in a gadgetry-driven work environment. This article, therefore, explains the necessity of construction processes modelling and how it should be implemented using international standards. Without the use of international standards, the construction industries miss-out on the benefits of operating in a digital work environment because of the clumsiness associated with modelling of information using manual methods.

Challenges of Modelling Contextual and Social Competencies Necessary for Managing Construction Processes

"If it isn't broke, don't fix it" – construction industry mantra

As the worldwide construction industry undergoes a paradigm shift driven by the adoption of BIM (Eadie et al. 2015), some owners and operators are yet to discover the added value of BIM in their respective areas of interest, especially the information management within their organizations (Bosch et al. 2015). Anecdotal evidence shows that experienced construction management workforce have a rule of thumb that prefers proven construction processes to new ones because the former have served the industry over the years need not be changed for the sake of change than the later. Meaning that before introducing change, there should be evidence showing that new approaches could outperform current ones. It could, therefore, be argued that modelling process information using BIM requires robust scrutiny and evidence-based data that could sway industry decision-makers to adopt it.

According to Kassem et al. (2015), BIM is the process of generating, storing, managing, exchanging, and sharing building information in an interoperable and reusable way. The critical issue has been to operationalize the interoperable know-how that underpins decision-making on construction processes so as to ease the justification and estimation of the resource consumable at a given time period of the project. Even though there is a perception that BIM uptake would continue increasing in the short term, enforced Level 2 BIM (BS 1192-4 2014) coupled with client demand has been the cardinal drivers of BIM thus far (Eadie et al. 2015). However, the increase in the uptake of BIM in its current form does not address the challenges of modelling processes that are critical to smooth operationalization of construction projects. Construction processes, by nature, encompass technical, contextual, and

behavioral (or social) competencies that are necessary to achieve project excellence (International Project Management Association (IPMA) 2018). It implies that one should manage people, processes, resources, results as well as project purpose. However, for construction process specialists to model the necessary data from the desired level of competencies, they would have to utilize and go beyond current BIM standards and guidelines (BS 1192-4 2014; BS 1192:2007+A2 2016; ISO 10303-1 1994; ISO 16739 2013). Such an achievement is desired, but highly unrealistic as at 2018 because the industry largely hovers on Level 2 BIM under the COBie code of practice (Eadie et al. 2015; BS 1192-4 2014; Specialist Engineering Contractors' (SEC) 2014). Therefore, the challenge for modelling construction process information lies with the top-down BIM initiative strategy because it focuses more on strategy and less on data process modelling.

Frailty of Top-Down BIM Initiatives

The full benefits of BIM for construction management could only be realized when the industry moves to a fully interoperable model (Level 3 BIM of COBie code of practice) – by file sharing system or by database system, with the capability to model technical and commercial data for the whole project (Specialist Engineering Contractors' (SEC) 2014). Such an aspiration could be realized if construction management research could redirect the energy on process data modelling using international standards (BS 1192-4 2014; ISO 10303-1 1994; ISO 16739 2013). Currently, construction processes have unlimited approaches through which they could be modelled mainly because of the varied nature of data types (ISO 10303-1 1994). For instance, construction process model would not only depict schedule data but also contract documentation to model legal information necessary to operationalize the project (Jamil and Fathi 2018); contracts to model risks and responsibilities of project stakeholders (Construction Industry Council (CIC) 2018); and the expert knowledge to model best practice from construction managers (Khosrowshahi and Arayici 2012; Kähkönen and Rannisto 2015). Khosrowshahi and Arayici (2012) opined that BIM implementation is a major change management task, involving diversity of risk areas. The identification of the challenges and barriers is therefore an imperative precondition of this change process. While generic preconditions have been explored over the past decade, there is a gap in addressing fundamentals of process modelling with regard to construction processes and the competencies of managing projects. The major factor has been the "abstract" nature of the data types needed to model processes.

Despite the realization of the need to revisit the modelling of construction processes, BIM implementation strategies tend to focus on organizational, cultural, and management-related action points. For instance, Khosrowshahi and Arayici (2012) proposed three structured patterns to systematically tackle technology, process, and people issues in BIM implementation. These are organizational culture, education and training, and information management (Khosrowshahi and Arayici 2012). Similarly, Aranda-Mena et al. (2009) identified mechanisms of informing project management practice on the business benefits of building information modelling (BIM) adoption. They found that there was a need for "shared understanding on business drivers to adopt BIM for managing the design and construction process of building projects ranging from small commercial to high-rise" (Aranda-Mena et al. 2009). Motawa and Almarshad (2015) opined that the "next generation of BIM should seek to establish the concept of Building Knowledge Modelling (BKM)". They argued that BIM applications in construction, including those for asset management, had mainly been used to ensure consistent information exchange among the stakeholders (Motawa and Almarshad 2015). Yet BKM is needed to utilize knowledge management (KM) techniques into building models to advance the use of these systems (Motawa and Almarshad 2015). Motawa and Almarshad (2015) proposed a "BIM module to capture relevant information and case-based reasoning (CBR) module to capture the operational knowledge of maintenance activities". The structure of the CBR module was based on analysis of a number of interviews and case studies conducted

with professionals working in public BM departments (Motawa and Almarshad 2015). The suggestion departs from the international initiative articulated in (ISO 16739 2013); the critical issue is to address the challenge at data model level using Express modelling language. Even though the current BIM strategies promote data sharing, knowledge is kept by those who possess it, mainly because their decisions are not easily modelled due to lack of mechanisms to do that. Project management practices in construction refer to, inter alia, process-based modelling in order to plan and control the delivery of projects as efficiently as possible and within health and safe working environment. The ISO standard for IFC, using STEP modelling language, has established the route way to neutral modelling of building information of all sorts, including both explicit and tacit knowledge. However, the challenge has been the creation of user-friendly interfaces that could model tacit knowledge, within a dynamic construction management environment.

Approach to Developing a Procedure of Modelling Construction Processes

The main approach to developing a procedure of modelling construction processes involved collection of information from practitioners and academics (Saunders et al. 2009; May 2011), whereby questions were asked with regard construction processes and the detailed explanation and justification (Rosenthal 2016). The model information came from practitioners in the United Kingdom (UK) (Strata.com 2017; Rose et al. 2015; Sounderpandian 2008). Professional construction personnel were asked to explain how BIM implementation strategies address modelling of construction management processes with a view to improving the capturing both tangible and intangible information. Six themes have been used to explain, and they are (i) perception of innovation in modelling construction process data, (ii) value addition of data models to construction processes, (iii) perception of ultimate benefits of data models, (iv) modelling systems information, (v) modelling sustainable construction processes, and (vi) models based on international standards.

Perception of Innovation in Modelling Construction Process Data

The initial theme was to assess the perception of innovation in modelling construction process data. By innovation, it was envisaged that BIM could be perceived as a vehicle for modelling technical as well as commercial data (Murphy 2014). The results indicated that there is a strong perception that BIM was addressing strategic competencies at the expense of technical and operational processes. Discourse on modelling construction processes was only perceived to imply "Gantt charts" and schedule related data. In reality, there are a myriad of key competencies for construction process which would have been modelled, but the means to model them is limited at best.

Value Addition of Data Models to Construction Processes

According to Bosch et al. (2015), owners and operators are presumably yet to discover the added value of BIM for maintenance and information management within their organizations. Construction processes were more complex than building maintenance; hence, it was critical to explore "sources of inefficiency and ineffectiveness" of BIM. Bosch et al. (2015) found that current added value of BIM in the operations stage was marginal, mainly because of the challenges of alignment between the supply of and demand for information and the context-dependent role of information (Bosch et al. 2015). Therefore, the second question related to the perception that data models could add value to construction processes. The rationale for this question was to assess how BIM was assessed with relation to existing construction processes. Practitioners felt that value addition was represented through 4D simulation of schedule and resource planning. The same reason was cited by Li et al. (2015). The industry struggles to capture data models with information from the wider supply chain on construction objects. This weakness is compounded by the scanty nature of

construction and commercial data because the nature of this type data is mainly abstract and dynamic.

Perception of Ultimate Benefits of Data Models

Lindkvist (2015) opined that "BIM offers a holistic approach to building projects across a number of practices". However, projects have a relatively short-term benefit of using BIM with 80 per cent of the cost of an asset spent in operations. The ultimate benefit of BIM is when the information which the end user inherits from building projects creates value that occurs over a long period of time (Lindkvist 2015). Therefore, the questions regarding the perception of ultimate benefit of data model were aimed at assessing if construction practitioners had a long-term view of BIM. The response shows that 83% felt that construction management processes are critical in assuring the asset owner throughout the life cycle of the product. However, there was an overemphasis on the schedule, resource management, and commercial management.

Modelling Systems Information

Practitioners were asked how the deal with data models for various building systems necessary to operate a facility. Love et al. (2015) argued that BIM models emphasized the integration of software packages for architectural, structural, heating ventilation and air conditioning, and hydraulics, mainly because such elements have scale, geometry, and can be visualized. They argued that there were many systems with no scale or geometry and that they could not be visualized (Love et al. 2015); yet they are equally vital to the development of facilities. Therefore, practitioners argued that they buy off-the-shelf data models for systems information. The response shows that just like construction practitioners found it hard to model systems information, the same goes for construction management processes. It is prudent to learn from systems information models (SIM) and use a system of isolating classes that have not been instantiated.

Modelling Sustainable Construction Processes

For BIM to make a positive impact on sustainable construction, it would have to facilitate the modelling to Level 3 (BS 1192-4 2014; Specialist Engineering Contractors' (SEC) 2014; Alwan and Gledson 2015). In such a situation, the role of modelling standards such as COBie cannot be underestimated (Alwan and Gledson 2015). Therefore construction practitioners were asked if they were modelling construction processes that enhanced sustainability in the industry. Construction practitioners felt that they had not reached the stage where they could model all elements and processes to promote sustainable construction. This shows that there is a realization that process of instantiating particular classes within existing data schema such as COBie has been challenging, meaning that models that claim to contain robust building data have less information than they purport to possess.

Models Based on International Standards

Construction practitioners were asked about the role of international modelling standards for capturing construction process models. Alwan and Gledson (Alwan and Gledson 2015) assessed the use of COBie data schema for building asset modelling. Hence, the question on the role of standards was critical to this research. The response shows that construction practitioners had a strategic awareness of the role that international standards on data models played in the construction industry. However, the perception of standards was attributed to regulating how the industry and its stakeholders conducted themselves in the BIM working environment. The response indicates that there has been a gap as to how industry could contribute to the use of data models such as ISO 10303-1 (1994) and ISO 16739 (2013), which focus on building product and process representation.

Discussion of the Procedures for Modelling Construction Process

Currently, the industry should rely on BIM as a way of modelling construction processes because

of the ability to capture both tangible and intangible data. However, there is a challenge with the current BIM schema because its construction management processes largely remain outside data models because of the abstract nature of the data that represents the said processes. For example legal information of a construction project cannot be modelled as an "object," yet it is critical to the construction process. Legal information is of abstract data type, critical to the management of stakeholder responsibilities, but has challenges to model within the BIM environment (Olatunji and Akanmu 2015). Kähkönen and Rannisto (2015) argued that construction project management is heavily built around document control and relating events such as change orders, submittals, transmittals, and requests for information; hence, there is a reliance on electronic data/document management systems (EDMS).

However, it could be argued that EDMS offer a limited solution to modelling construction processes. This implies that EDMS do not fully mitigate software interoperability challenges of a typical construction process. EDMS do suffer from the lack of software interoperability, because it only speeds up the manual way of working and does not fundamentally address interoperability as per international BIM standards. Davies et al. (2017) opined that the potential for BIM to improve processes is documented, but few projects realize that potential.

This is because construction processes are laden with a myriad of undocumented tasks, events, and decisions related to logistics, health and safety (Riaz et al. 2017), and the impact on delivery schedules, and the supply chain and the milestones. Such challenges cannot be ignored any longer for the industry to move to Level 3 BIM (Specialist Engineering Contractors' (SEC) 2014) (SEC, 2014), or else the BIM working environment would continue being insignificant in the operational life of facilities (Edirisinghe et al. 2017). It can be argued that adopting strategic protocols for implementing BIM has an insignificant drive on the process of data modelling (Mei et al. 2017). Making BIM mandatory does not address the challenges of modelling construction processes; this should be a focus of researchers within that field (Day 2011).

Therefore, the goal for improving modelling construction process needs to focus on meta-analysis of the pertinent data in Level 3 BIM (Noor and Yi 2018); else the status quo is likely to have a negative impact on future construction workers because knowledge is being lost through a natural process such as retirement of the most experience people (Sfakianaki 2015), whose knowledge cannot be captured and shared with new entrants to construction management.

Conclusion

As the construction industry continues to claim benefits for adopting BIM, the modelling of construction management processes and their embedded knowledge remain stagnant. This is mainly because of the abstract nature of the data that typify construction processes. As a result, construction processes are laden with a myriad of undocumented tasks, events and decisions related to logistics, health and safety, and the impact on delivery schedules and the supply chain and the milestones. Such challenges cannot be ignored any longer for the industry to move to Level 3 BIM, or else the BIM working environment would continue being insignificant in the operational life of facilities. Strategic protocols for implementing BIM have an insignificant drive on the process of data modelling. Making BIM mandatory does not address the challenges of modelling construction processes.

Definition

Computer shogi is a field of artificial intelligence involving the creation of software programs capable of playing shogi, the Japanese form of chess.

Introduction

Computer shogi was first developed in late 1974 by Takenobu Takizawa and his research group. It has been steadily improved by researchers and commercial programmers using game tree making and pruning methods, opening and middle game databases, and feedback from research into tsume-shogi (mating) problems. The strength of computer shogi has been measured by watching and studying many games between computer programs and professional players and has reached that of top-level human players. In the remainder of the article, section "Computer-Computer Games" describes the history of computer-computer games. Section "Computer Shogi Players" describes the programs that played them, and section "Computer-Human Games" describes the history of human-computer games.

Computer-Computer Games

Yoshiyuki Kotani and Takenobu Takizawa jointly established the Computer Shogi Association (CSA, Takada 2014) in 1986. This organization started organizing computer shogi tournaments called the World Computer Shogi Championships (WCSCs), in 1990 (Takizawa and Grimbergen 2001). The tournaments are supported by Nihon Shogi Renmei (the Japan Shogi Association or JSA).

The following are the policies of WCSCs declared on January 23, 2012.

1. The WCSC tournaments are held for the purpose of determining the strongest computer shogi program at the time under conditions of fair and impartial operation.
2. The CSA imposes no restrictions on the hardware or software of any WCSC entrant or on persons entering the hardware or software.
3. The CSA supports the interchange of ideas among hardware/software developers who enter their products in WCSC tournaments.

Table 1 shows a summary of WCSC results. Ten programs have won the tournaments. Kanazawa Shogi has won five times, IS-Shogi and Gekisashi four times each, YSS three times, Bonanza and GPS Shogi twice each, and Eisei Meijin, Morita Shogi, Bonkras, and Apery once each. The 22nd WCSC was held on May 3–5, 2012. Forty-two teams (including one invited) entered, with GPS Shogi winning the championship for the second time. The 23rd WCSC was held on May 3–5, 2013. Forty teams (including

7	Shueso	3–	2–	4–	6–	1+	5+	8–	2.0	8.0	0.0
8	YSS	2–	1–	3–	4–	5–	6–	7+	1.0	2.0	0.0

one invited) entered, with Bonanza winning the championship for the second time. The 24th WCSC was held on May 3–5, 2014. Thirty-eight teams entered, with Apery winning the championship for the first time.

The 22nd WCSC tournament had 42 computer players (including one invited). GPS Shogi was the winner, but if Ponanza had beaten GPS Shogi in the last game, then Tsutsukana, Ponanza, or Puella alpha would have been the winner. The final round results are shown in Table 2.

The 23rd WCSC tournament had 40 computer players (including one invited), and Bonanza was the winner. After the preliminaries had narrowed the field down to eight, those eight played a round robin (each player playing the other seven players once) to determine the winner. The results were close, with the top three programs losing twice, while every program won at least once. This indicates that the top programs were comparable in strength. For example, GPS Shogi would have been the winner if it had won the last game. If Shueso, which finished seventh, had beaten YSS, which finished eighth, in the last game, Ponanza would have been the winner. The final round results are shown in Table 3.

The 24th WCSC tournament had 38 program entrants, with Apery being declared the winner. Both Apery and Ponanza won five games and lost two, but Apery got the nod on tiebreak, even though YSS beat both of them. Ponanza was thus runner-up as it had been the year before, while YSS had to settle for equal third place. The YSS program entered the WCSC tournaments 23 times and never finished worse than equal eighth in any of them. Both Ponanza and NineDayFever would have won the tournament if they had won their last game. The final round results are shown in Table 4 (Takizawa 2014).

Computer Shogi Players

Most computer shogi programs carry out minimax tree searches enhanced by techniques in computer chess and by other completely new ideas. In this

Contemporary Computer Shogi, Table 4 24th WCSC final results (May 5, 2014)

Rank	Player	1	2	3	4	5	6	7	Pt	SOS	SB	MD

section, "The Art of Computer Shogi" describes the art of computer shogi, and "Brief Description of the 24th WCSC Winner Program" gives a brief description of the 24th WCSC winner program, Apery.

The Art of Computer Shogi

Many computer shogi programs use alpha-beta pruning, PVS (principal variation search), quiescence search, aspiration search, null move (forward) pruning, futility pruning, killer heuristic, history heuristic, iterative deepening, transposition hash tables, and singular extension, adopted from chess programs. A minimax tree for shogi usually has a larger branching factor in the endgame than in the opening. The row branching factor on average is about 80, and it is known that the factor is effectively reduced to about 3 by using pruning techniques.

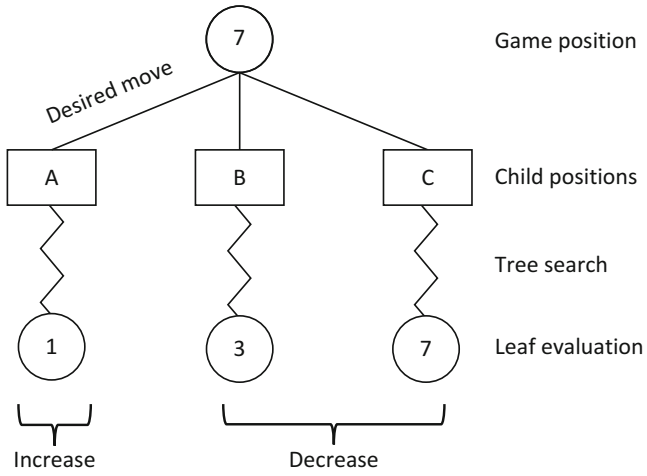
Large-Scale Optimization for Evaluation Functions

Heuristic search is a powerful method in artificial intelligence. In the case of chess, it is capable of deciding a plausible move after expanding a large minimax game tree with heuristic leaf evaluations. The quality of such heuristic evaluations is crucial for making strong computer chess players. Researchers have made substantial efforts in a quest to create effective evaluation functions by using machine learning techniques in various games (Fürnkranz 2001). Shogi is probably one of the more interesting games to see successful examples of machine learning of evaluation functions.

In 2006 Bonanza, a program developed by Kunihito Hoki, demonstrated a practical use of machine learning of evaluation functions in WCSC and won the competition. The learning method consists of subsequent steps: prepare a set of grandmaster game records, a search function, and a linear weighted evaluation function and decide the initial weights in the function. Give positions in game records to the search function and compute agreements between the search results and the recorded moves. If more search results agree with recorded moves, then the weights are probably better. To adjust the weights, iterative procedures of numerical minimization techniques are carried out. In this way, the learning procedures optimize the weights to control the minimax tree search results.

Figure 1 illustrates such a learning procedure as applied to chess. Assume the game position has three legal moves and a grandmaster has just played a move to reach child position A. The procedure carries out a tree search to examine the three child positions that could have been reached on the move and obtains search value 1 for position A, 3 for position B, and 7 for position C. In this case, the tree search recognizes that C is the best, B is the second best, and A is unfortunately the worst. Under this circumstance, the learning procedure adjusts the value of the leaf evaluation rooted at A higher, and those rooted at B and C lower.

Such learning methods were investigated in computer chess because the game scores of grandmaster games were a common way to learn chess, not only for computer players but also human players. Assume that one has a position reached in a game score and the desired move is the one that was actually played. A chess program



Contemporary Computer Shogi, Fig. 1 An illustration of evaluation learning procedure

has an evaluation function $e(p,\boldsymbol{w})$, where p is the game position and the feature weight vector $\boldsymbol{w}$ contains the parameters to be adjusted. Now consider a simple intuitive goal: make the results of a one-ply search agree with the desired move, where the search selects the highest evaluation value. Thus, w should be adjusted so that the desired move has the highest evaluation of all the moves. This goal can be written as a minimization problem with an objective function:

$$J_H(\boldsymbol{w}) = \sum\nolimits_{m'} H(e(p.m', \boldsymbol{w}) - e(p.d, w)) \quad (1)$$

Here, $p.m$ is the child position reached after move m, d is the desired move, index m' runs for all legal moves except d, and $H(x)$ is the Heaviside step function, i.e., $H(x)$ equals 1 if $x \geq 0$ and 0 otherwise. Because this objective function counts the number of moves that have an evaluation value greater than or equal to that of the desired move, a better w can be found by minimizing Eq. 1.

In chess, several studies have been made on the basis of the objective function Eq. 1 (e.g., see Meulen 1989). However, numerical minimization seemed to present practical difficulties. To overcome such difficulties, Marsland (1985) used some continuous functions instead of the non-continuous step function $H(x)$ so that the gradient vector would help to reduce the function value numerically. Moreover, Hsu et al. (1990) used evaluations of leaf positions of the principal variations instead of using the direct evaluations of p. m' and $p.d$ to get better learning performances. Furthermore, Tesauro (2001) used a continuous approximate of the step function. Although it seemed that such learning methods would be able to adjust hundreds of weights to have reasonable values, fully automated learning of the chess evaluation functions still remains a challenging goal. For example, developers have reported that the majority of the features and weights in Deep Blue were created/tuned by hand (Campbell et al. 2002).

It turned out that such machine learning by using grandmaster games was also useful in shogi. Hoki et al. proposed a method, Minimax Tree Optimization (MMTO, Hoki and Kaneko 2014), to learn the evaluation function of a practical alpha-beta search program. They used grid-adjacent update, equality constraint, and l_1 regularization to achieve scalability and stability. Their objective function with modified gradient vectors was to be able to optimize the values of 13 shogi pieces with reasonable numerical accuracy and to adjust 40 million parameters for strength. Hoki had proposed an earlier version of MMTO in 2006 (Hoki et al. 2006) and implemented it in the shogi program Bonanza, winning the WCSC championships in 2006 and 2013. After 2006, it became famous and has often been referred to as the "Bonanza method." Recent computer shogi players have evaluation functions, where the weights are learned from professional players' game records.

Many machine learning techniques that do not require grandmaster game records have also been applied to shogi. However, the adjustment of the full weights in the evaluation function remains a challenging goal. The studies that have been published so far have adjusted only piece values or a small part of the feature weights in the evaluation functions.

Consultation Algorithm

Much research that has compared problem-solving by groups with that by individuals has been carried out in the field of cognitive science. Shaw conducted an experiment that compared the efficiency of problem-solving by a group and that by individuals in 1932, using a missionaries-and-cannibals problem (Shaw 1932). Many researchers used simple logic problems of this type from the 1940s to the 1950s and found that groups were able to outperform individuals. These results supported the old proverb that "two heads are better than one."

Althöfer et al. (2003) have carried out studies since 1985 on chess or the game of Go in research on the selection of moves in thought games. They proposed a system called 3-Hirn that consists of two computer programs and a human chess player, where the human selects a move from the programs' outputs. They demonstrated that the system enabled the programs to improve their ratings by about 200 points. They carried out almost the same experiments in Go or other games, and through them they demonstrated the system's efficiency.

From this, one gets the idea that an ensemble of game programs may be able to play a better move than an individual program does. Although many sophisticated ensemble-based systems in computer science have been built with the aim of achieving better performance, designing such systems in computer games still remains a challenging task.

One of the methods that could be used to build such an ensemble-based system in shogi is the majority voting method. Obata et al. (2011) reported that majority voting in three famous programs (YSS, GPS Shogi, and Bonanza) produced better games than any of the three programs played individually. They also proposed a pseudorandom number (PRN) ensemble method. In this method, the ensemble is built using multiple copies of one base program, and each copy is diversified by adding random numbers to the evaluation function of the base program.

They researched these methods where a machine chose a move automatically without human intervention. Here, they defined "consultation" as a process that generates one answer on the basis of conclusions obtained by using two or more different thinking processes. They considered various methods of "consultation" by computers and concluded that the "majority voting system" might be one of the simplest systems, in which a majority opinion is adopted from various opinions. Although the system was very simple, they showed its effectiveness in their experimental results.

Sugiyama et al. (2011) examined another approach, one of combining multiple programs. In carrying out this approach, they used a new selection rule that selects the player that yields the highest evaluation value. They called this method the "optimistic ensemble system" and reported that it often outperformed the "majority voting system" when multiple computer programs were prepared by using the PRN ensemble method.

Hoki et al. (2014) examined these ensemble systems in computer chess. The results of their experiments showed that both the "majority voting system" and the "optimistic ensemble system" were efficient in computer chess.

Two advantages of the "consultation" method are known. First, it can use a loosely coupled computing environment. Because it is simple and fault tolerant, it can always be an alternative when a large-scale distributed environment is available for strength. Second, it has a high degree of generality and is orthogonal to other parallel search techniques. It can function efficiently with multiple different programs even when each program utilizes parallel search techniques.

Research on consultation systems in games is still in the infancy stage. So far, the effectiveness of simple majority voting has been examined only for shogi and chess, where computer players perform minimax tree searches, and in Go, where

computer players perform Monte Carlo tree searches.

Realization Probability Search

When computer players start to play a shogi game, moves previously made by professional players have already been collected and categorized and their probabilities calculated in the program. These moves include capturing and recapturing pieces, promoting a rook or bishop to gain a material advantage, checking, and so on. During the course of the game, the players control tree expansions based on these probabilities, i.e., if the multiplied probability of a move history from the root to the current position is higher than a threshold, then the program searches deeper. Tsuruoka et al. (2002) proposed this algorithm and implemented it in the Gekisashi program, and with it they won WCSC titles in 2002, 2005, 2008, and 2010.

Distributed Parallel Search

The first computer shogi program using a multiprocessor system was the Super Shogi program developed by Hisayasu Kuroda in 1997, which used an eight-computer system. In 2012, the GPS Shogi program developed by Tetsuro Tanaka and Tomoyuki Kaneko et al. used 320 processors (666 cores in total) and won the 22nd WCSC title (Kaneko and Tanaka 2012).

Tsume-Shogi (Mating Problem) Solver

In addition to ordinary minimax searches, a computer player often uses an additional search function dedicated to finding a long mate sequence. The techniques used in tsume-shogi functions derive from studies on solving such mating problems. Unlike in chess, in shogi the number of possible moves in the endgame is the same as the number of possible moves in the middle game. Therefore, an efficient AND/OR tree search algorithm are needed for solving tsume-shogi problems. Recent state-of-the-art solvers employ the df-pn search algorithm proposed by Ayumu Nagai, which is capable of solving most existing tsume-shogi problems (Kishimoto et al. 2011). Computer players also often use a hard-coded function dedicated to finding one- or three-ply mate sequences.

Brief Description of the 24th WCSC Winner Program

The Apery program, which was developed by Takuya Hiraoka, had a Stockfish-like search function (Stockfish is a strong open source chess program). Over the past 3 or 4 years, the effectiveness of the chess search function in shogi has become famous, notwithstanding the differences in the rules between the two games. Using chess search techniques, Apery achieves performance improvements by using additional functions such as a one-ply mate search function.

Apery also has a Bonanza-like evaluation function. It evaluates shogi positions by using a three-piece square table that evaluates all combinations of a king and other two-piece locations. Because the combinations always contain one or two kings, the evaluation function is sensitive to the distance between kings and other pieces. In shogi, the distance from a king is a vital feature. Most shogi pieces have limited mobility, and those that are located far from the kings are for the most part useless, especially in the endgame. Since the source codes of Bonanza version 4 appeared online in 2009, it seems that the evaluation function's performance has advanced in both computational speed and evaluation accuracy. Hiraoka believes that Apery's evaluation function does not reach the highest level and has some room to improve. One of the difficulties in creating such a highest-level evaluation function is that machine learning of evaluation functions requires a tremendous amount of computational resources.

Hiraoka believes that Apery's rating is 200–250 points below that of the top programs and considers that Apery won the 24th WCSC for a number of reasons. First, the tournament concluded with a round robin of eight entrants, so only seven games determined the tournament winner. Second, on the basis of a "pawn toss" method, Apery moved first four times and second three times. This is important because the player moving first has the initiative. Statistics show that

in professional shogi, the player who moves first wins about 52 % of the time; Apery's corresponding percentage playing against other programs is 56 %. Third, a relatively short time control was used in the tournament (25 min for the whole game with no time-shortage countdowns), and while the top programs utilized a loosely coupled computing environment, Apery did not. Because Apery was free from distributed computing overheads, the short time control increased its winning chances. Fourth, Apery played the openings quite strongly since its opening "book" contained the moves computer players had previously played that were available in floodgate (http://wdoor.c.u-tokyo.ac.jp/shogi/). On the other hand, the other entrants did not seem to focus on the best moves as given in opening books.

Computer-Human Games

In 1997, when IBM's "Deep Blue" program beat the world chess champion Gary Kasparov in a six-game match, the strongest computer shogi program was only a little stronger than an average club player. The top programs reached the professional 4-dan level in 2010 and have now reached the top human-player level. Table 5 summarizes the results of computer-human games that have been played to date.

The first game between a female professional shogi player and a computer shogi program was an exhibition game played on July 29, 2001 at the Mind Sports Olympiad in Japan. Each player had 15 min for the whole game plus a 60-s time-shortage countdown. Yamato Takahashi, the professional player, moved first and won her game against IS-Shogi. After the game she said, "IS-Shogi's strength is about 1-dan in the opening, 4- or 5-dan in the middle game, and 3- or 4-dan in the endgame. For the game as a whole it is not 1- or 2-dan but 3- or 4-dan."

On September 19, 2005, Hokkoku Shimbun sponsored a game between the TACOS program and Takanori Hashimoto, an 8-dan professional. Hashimoto eventually won, but TACOS had the

Contemporary Computer Shogi, Table 5 Game results: professional shogi players vs. computer shogi programs

Date	Event	Professional human player	Computer	Winner	Time control (countdown)
2007.3.21	Daiwa Shoken Hai Special Game	Akira Watanabe (Ryu-O titleholder)	Bonanza	Human	2 h (60 s)
2011.12.21	Den-O-Sen Practice Game	Kunio Yonenaga (Lifetime Kisei titleholder)	Bonkras	Computer	15 min (60 s)
2012.1.14	First Shogi Den-O-sen	Kunio Yonenaga (Lifetime Kisei titleholder)	Bonkras	Computer	3 h (60 s)
2013.3.23	Second Shogi Den-O-Sen	Koru Abe (4-dan)	Shueso	Human	4 h (60 s)
2013.3.30		Shin'ichi Sato (4-dan)	Ponanza	Computer	
2013.4.6		Kohei Funae (5-dan)	Tsutsukana	Computer	
2013.4.13		Yasuaki Tsukada (9-dan)	Puella alpha	draw	
2013.4.20		Hiroyuki Miura (9-dan)	GPS Shogi	Computer	
2013.12.31	Den-O-Sen Rematch	Kohei Funae (5-dan)	Tsutsukana	Human	4 h (60 s)
2014.3.15	Third Shogi Den-O-Sen	Tatsuya Sugai (5-dan)	Shueso	Computer	5 h (60 s) (chess clock)
2014.3.22		Shin'ya Sato (6-dan)	Yaneura-O	Computer	
2014.3.29		Masayuki Toyoshima (7-dan)	YSS	Human	
2014.4.5		Taku Morishita (9-dan)	Tsutsukana	Computer	
2014.4.12		Nobuyuki Yashiki (9-dan)	Ponanza	Computer	
2014.7.19–20	Third Shogi Den-O-Sen Rematch	Tatsuya Sugai (5-dan)	Shueso	Computer	8 h (60 s) (chess clock)

advantage in the middle game. After this the JSA prohibited professional players from playing against computer players in front of an audience without its authorization. In the same year, Gekisashi was invited to an amateur Ryu-O tournament. Placing 16th, it was evaluated as being comparable in strength to top-level amateur shogi players.

On March 21, 2007, a game was played between Bonanza and Akira Watanabe, holder of the prestigious Ryu-O championship title. Sponsored by Daiwa Securities, it was the first official game between a professional shogi player and a computer player since the abovementioned Hashimoto-TACOS game in 2005. It was a very close game, with Watanabe eventually winning. Watanabe recently said that he was lucky to win because in a critical position, a professional human player can find a winning move relatively easily, but this is not so for computer shogi programs.

On October 11, 2010, Ichiyo Shimizu, one of the top female professional players, lost a game against the computer shogi system Akara2010. The game was sponsored by Komazakura (JSA Ladies Professional Players Group), the Information Processing Society of Japan, and the University of Tokyo. Each player had 3 h for the whole game plus a 60-s time-shortage countdown. The Akara2010 system employed the majority voting method using four existing programs combined with a distributed search method (Hoki et al. 2013) to enable it to use a large number of computers.

The first Den-O-Sen was held on January 14, 2012. This was a game played between a retired professional, the late Kunio Yonenaga, and the Bonkras computer program that had won the 21st WCSC. The game was sponsored by the JSA, Dwango, and Chuokoron-Shinsha, Inc. Each player had 3 h for the whole game plus a 60-s time-shortage countdown. Taking advantage of having the initiative that comes with moving first, Bonkras won the game.

The second Den-O-Sen, sponsored by Dwango and the JSA and held in March–April 2013, matched five human players and five computer programs. Each player had 4 h for the whole game plus a 60-s time-shortage countdown. The programs had taken the first five places at the 22nd WCSC. Table 1 shows the match results. It had been predicted that the human players would win the match with four wins and one loss, but the prediction was wrong; the programs took the match with three wins, one draw, and one loss. It was a major surprise that the very high-ranking professional Hiroyuki Miura (9-dan) was defeated by GPS Shogi (Takizawa 2013).

The third Den-O-Sen (July 2014), like the second, matched five human players and five computer programs. The programs had taken first through fifth places at the first Den-O tournament (a November 2013 all-computer tournament sponsored by Dwango and the JSA), with Ponanza the winner. Again it was predicted that the human players would win the match with four wins and one loss, this time because the programmers had not changed their programs after the Den-O tournament and the professional players had had a chance to study them. But again the prediction was wrong; this time the programs took the match with four wins and one loss.

Summary

The top computer shogi programs have already come close to the top human-player level. About 10 years ago, Yoshiharu Habu, holder of the prestigious Meijin championship title, predicted that the top programs would get close to the top human-player level in 10 years. His words were prophetic. Many professional players now understand how strong top computer programs have become, as do many people who have seen the results of the Den-O-Sen competitions or read about them in newspapers.

Computer shogi programs have become the helpful partners of professional players, who now use them in their studies. For example, 8-dan Daisuke Nakagawa observed the 18th WCSC and also the exhibition game between the Tanase Shogi program (the tournament runner-up) and the top amateur player Yukio Kato, which Tanase Shogi won. After studying this game, Nakagawa won his next three games in professional

competition, including one against Akira Watanabe, one of today's very top-ranked players. Another example is 9-dan Toshiyuki Moriuchi, who studied Ponanza's moves and used them to beat the superior Yoshiharu Habu in their 2013 match for the Meijin championship title.

The game of chess as played between humans is still vibrant and active, although computer chess programs are now stronger than the strongest human players. The same thing is likely to happen in the next 5 years for the game of shogi. However, while computer programs have come closer to unraveling the deepest mysteries of chess than they have of shogi, the fathomless depths of both games will continue to challenge researchers in the future.

Counter-Strike Global Offensive, an Analysis

Daniel Kasnick[2], Sam Romershausen[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Esports; First-person shooter; Free-to-play; Loot box; Mod

Definition

First-person-shooter (FPS) = a genre of games where the camera focuses on a gun (or other weapon) where the objective is to eliminate specific targets.

E-sports = a sports competition with video games as the focus rather than traditional sports.

History of Counter-Strike Global Offensive

Counter-Strike: Global Offensive (often abbreviated as CS:GO) is a team-based online first-person-shooter for Windows, OS X, Linux, Xbox 360, and Playstation 3 platforms in 2012. CS:GO was developed and published by Valve (Moore 2018). Counterstrike was originally a mod for a game, also developed by Valve, called Half-Life. A mod is an unofficial change to a video game created by players of the game. Mods can range from changing the way a game looks to changing the way a gamemode would normally work, in essence creating its own unique identity.

Since the early 2000s, Counter-Strike has evolved into its own standalone game franchise. CS:GO. In 2018, Valve changed CS:GO's pricing

method, switching to a free-to-play model by using revenue from cosmetic items to supplant the up-front cost. Free-to-play games allow access to a large part of the gameplay activities without up-front monetization. In-game purchases for cosmetic items offset the lack of up-front revenue.

Counter-Strike's most popular feature is its online matchmaking. It is a 5v5 team-based game that involves two sides, called the Terrorists and Counter Terrorists. The Terrorists are responsible for planting a bomb and ensuring that it explodes, while the Counter Terrorists are responsible for defending bomb sites and defusing the bomb. Players do not respawn after they die. Each team must strategize and/or counteract the opposing team's plays and be able to break through enemy lines or keep their defenses up; however, the fast pace of Counter Strike means that constantly being able to communicate efficiently and thoroughly to teammates can prove to be a challenge. For example, if a team's takeover strategy failed, the team has to quickly think of a new strategy in order to adapt, rise, and overcome. There are many problems that a team must solve on the fly, but are not directly told. Some include communication, playing as a team, doing your part in the match, etc. There are many scenarios that make the game enticing enough that most seasoned veterans return season after season; the team that either kills all other players on the opposing team or blows/defuses the bomb wins the round. CS:GO has a large competitive scene. There are massive competitive tournaments with many different professional Counter Strike players that play for sometimes millions of dollars. These tournaments, such as DreamHack, ESL, and more, hold some of the most viewed e-sports tournaments.

CS:GO allows players to host their own servers that have their own modded game modes. Other fan-created game-modes include bunny-hop, which is hopping from platform to platform to reach the end in the fewest number of mistakes. There are some other game modes that have gathered an audience, but run on small private servers. There are other features that a large part of CS: GO's player base partake in. One of the major ones being skin trading. Skins are just customizable wraps that several artists develop. They can be obtained from loot boxes. A loot box is an item that holds several other random items that can be used to change an item's appearance, in-game equipment, and other gameplay elements. It is often used as a way to monetize a game further. Some forms of Loot Boxes have been speculated to be a form of gambling. Some exceedingly rare and exclusive items have been sold on markets for over $30,000 USD.

Counter-Strike: Global Offensive was well received by critics at the time of release, with most ranging from 8/10 to 9.5/10. It has a Metacritic score of 83 and a user score of 7.5 (Metacritic 2012). After an update in 2013, an economy around the in-game skins cultivated several websites that allowed users to gamble their skins, including underaged players. Valve took steps in the following months to dissuade gambling sites from operation. In 2018, several countries passed antiloot box laws as they determined that they were gambling; Valve changed the game in the Netherlands and Belgium to comply with these laws by preventing the opening of loot boxes.

Cross-cultural Game Studies

Yukiko Sato
Cygames, Inc., Shibuya, Tokyo, Japan

Synonyms

Comparative studies; Convergence; Cross-cultural studies; Game studies; Globalization; Localization

Definitions

Cross-cultural game studies aim to compare and clarify differences and similarities of games and culture across two or more cultures on a regional or national level. The elements of culture in game studies are understood as a shared way of thinking, behavior, language, value, belief, and gaming practices, which surround game cultures in the form of games as cultural artifacts, or as parts of subcultures formed by specific communities. Current cross-cultural game studies investigate and compare game contents, game markets, the gaming industry and production, player behavior as well as game and player interaction. Methods range from qualitative analyses, such as comparative case studies, literature reviews, empirical interviews, and text analysis, to quantitative methods of surveys, statistical tests, and natural language processing. The perspective of studying games and their surrounding contexts from cross-cultural lenses has potential to expand new findings and knowledge on video games and culture.

Culture in Game Studies

Game studies are increasingly focusing on game culture in diverse local contexts (Liboriussen and Martin 2016). Whether physically or in cyber space, in this era of digital transformation, video games, their creation and distribution, content and gaming experiences are consistently crossing cultural boarders, showcasing the complexity associated with understanding games and their surrounding phenomena. This obvious integration and transmission of culture and games opened new perspectives to study and clarify the differences and similarities of games and culture as well as its transition in several regions, which is signified by an increase in cross-cultural aspects in game studies. This entry introduces the concept of culture and games, and current research on games and culture conducted through the lens of cross-cultural studies.

The concept of culture is notoriously hard to define. Culture has been considered from a variety of academic viewpoints and theories, characterized by several layers, levels, or dimensions (Hofstede 2011; Schwartz 1999), and scientists have discussed how cultures evolve through globalization (Reinecke and Bernstein 2013). The culture of video games has been shaped from various interdisciplinary perspectives, focusing on game cultures understood as games as cultural artifacts, or as parts of subcultures formed by specific gaming communities, defined by social practices, and through the discourses of the video game industry, media, and academia (Shaw 2010). Mäyrä (2010) views culture as a shared way of thinking, behavior, values, and gaming practices among individuals in the micro- and macro-levels of society. Such cultures result in forming subcultures, which are visible aspects of specific language use, behavior, and beliefs among a particular community. In terms of levels of games and culture, Elmezeny and Wimmer (2018), p. 82) introduce

three levels of defining game cultures: 1) the macro-level focuses on the overall culture of games, gamers, and gameplay in regional or national fields worldwide, 2) the meso-level focuses on culture among multiple games or communities with unified characteristics, such as PS4 gamers and Nintendo gamers, and 3) the micro-level focuses on culture of a specific game or community, such as World of Warcraft culture or German FIFA culture.

In contemporary society, video games are the latest form of cultural expression, helping us to understand modern culture and society (Muriel and Crawford 2018). As games are becoming a major cultural influence, game studies evolved not only as a field focusing on games, playing, and related phenomena (Mäyrä 2008, p. 11) but also hold the power to critically analyze power relations in our culture and society by studying game contents, audiences, and production processes (Nieborg and Hermes 2008). Current game studies are formed by six major domains: 1) studying games as artifacts or texts (e.g., Mäyrä 2008; Schell 2008; Juul 2011), 2) analysis of player behavior (Charles et al. 2005; Braun et al. 2016), 3) globalization and localization of the games industry (Consalvo 2006), 4) game development (Engström 2020), 5) gaming culture (Muriel and Crawford 2018), and 6) interaction between game and player (Caroux et al. 2015). However, few have examined games and related phenomena from a cross-cultural perspective, that is, sought the difference and similarities among game markets, game production and design, game content, as well as the meaning and perception on games by game designers and players in geographically and socially different contexts.

Looking at the current situation in concern of video games, game developers and platforms from different cultures, such as Tencent (China), Sony (Japan), EA (America), and Ubisoft (France), compete on a global level, targeting local and global audiences (Newzoo 2020). Games are frequently developed through collaboration across culturally diverse regions. Death Stranding was for example created by the prominent Japanese game designer Hideo Kojima collaborating with Western actors and artists (Game Media 2020). Game contents produced in one culture are enjoyed in other cultures, for example games developed in East Asia are consumed by Western audiences (Consalvo 2006), influenced by localization processes (Mangiron and O'Hagan 2006). Game-related research so far has utilized a cross-cultural perspective to compare and understand the differences and similarities between game markets, production, design, and user experience. In this background, this entry introduces the strands of cross-cultural game research conducted on a macro level, which compare the overall differences and similarities among characteristics of culture of games, gamers, and gameplay on a regional or national level. This entry also discusses current themes and challenges of cross-cultural game studies.

Video Game Market

As the global video game market continues to grow, researchers study the history, expansion, and emergence of the games industry in global and local game markets and explains how the innovation of games and technology influence our contemporary and future culture and society. Dating back to the invention of digital games in the 1950s, the hit and crash of home consoles from the Magnavox Odyssey (1972) to the Atari 2600 (1977), the competition between Nintendo, Sega, and Sony in the early 1980s, joined by Microsoft in 2001, and mobile games proliferating in the present, researchers have been studying the process of how the game markets changes our culture (Wolf 2008, 2012). Looking back at the history of fast-moving video games leads to the realization of how conventional media, entertainment, and technology converge to create a new phenomenon and a new part of culture in our society (Wolf 2008).

Market analysts such as Newzoo (2020) track the developments in the rapidly changing global games market. They provide comparisons of market shares and growth for different regions. Unity Technologies (2020) releases detailed reports focusing on mobile gaming trends. Computer Entertainment Supplier's Association (2020) also delivers annual white papers to report the gaming trends in the world.

Within academia, Johns (2006) closely studies and compares the expansion of hardware and software production networks of game markets, focusing on three supra-regional sections, North America, Europe, and Asia-Pacific. Ip (2008) investigates the games market chronologically, to see how game titles and platforms created in different cultures evolved through convergence of technology and content. However, as Šisler et al. (2017) state, current research on games and focuses on particular regions, while smaller regions are ignored. As the games market further globalizes, partially through online and smartphone technologies, there are needs to systematically analyze differences and similarities in game markets from a broader perspective to understand how games and their meaning change in our globalizing society.

Video Game Industry and Production

Studies on game production, industry, and cultural influence is one of the earliest themes focused on in cross-cultural games research. As it is a challenge for academics to access information from the games industry (Engström 2019), this field of study sheds light upon how games are designed and developed, how developers are structuralized, and how industry across different regions merge to disseminate games in a different cultures. Previous comparative research heavily focuses on the difference between Eastern and Western game development, especially on the differences between Japan and the West. Compared to Western game design, Aoyama and Izushi (2003) note the pervasiveness of the manga and anime industry in the Japanese games industry. The similarities between Western countries and differences of the Japanese games industry are further studied by comparing the evolution and transition of the video games industry in the USA, the UK, and Japan. Johns (2006) claims that North American and European game companies became closer through internationalization, while Japanese game companies grew isolated, creating games influenced by the manga and anime industry. In contrast, Consalvo (2006) also explores the complex transnational relations between the Japanese and American games industries, arguing that the current (console) video game industry is a hybrid that mixes Japanese and American businesses practices and cultures (Consalvo 2006, p.118).

As studies on globalization and transition of major game industries continue, other researchers argue the importance to study smaller regions of game development. Studying the characteristics of game development in three different regions in the Nordic region, India, and China, Toftedahl et al. (2016) point out that the current understandings of video game development have been associated mostly with Japan and the USA, raising concerns to the standardization of the development practices of video game development and limitations to understand the development process in other regions. This shows one challenge of cross-cultural games research. Therefore, researchers capable of cross-regional and industry-academia collaborative research need to take the lead to conduct cross-cultural game development research in order to show the differences and similarities of global and local game industries, contributing to the next generation of game development.

Game Content

As game developers seek to sell their games globally, the process of adapting products, contents, and services to suit the players in each region plays a major role. Carlson and Corliss (2011) show how cultural differences influence game production and game content. Hence, localization is essential to enable video games to be played in a similar way in different markets (O'Hagan 2009). Arguably, it is important to ensure that players enjoy a game created in another culture in the context of their own culture (Mangiron and O'Hagan 2006). Localization involves making decisions about culturally appropriate images, character designs, translation, gameplay mechanics, the technical nature of software, and negotiation of national regulatory boards (Carlson and Corliss 2011). Case studies on cultural differences focusing on the translation of the original game and its localized version are conducted by O'Hagan and Mangiron (2004) and Mangiron and O'Hagan (2006), arguing that the cultural differences impact the characterization of the

main characters. Carlson and Corliss (2011) provide comprehensive examples of what kind of game contents are altered when media travel across national borders, for example how game designers consider to create a generic character instead of a specific one, alter the speed of characters movements to fit cultural preferences, as well as change how blood is displayed in a game due to rating board regulations. Ng (2006) studies how game contents differ between Asian regions, stating that players add new context to games, and also to the culture itself, by consuming and hybridizing with other popular culture.

Player Behavior and Experience

Analyzing the interaction of game and player within their respective contexts has been a central task of game studies (Mäyrä 2008). In cross-cultural games research, researchers have been analyzing the difference of users' playstyles, their perception of games. Game user related studies can be sorted by two axes of 1) research methods, that is, qualitative or quantitative and 2) target regions, that is, Asia-West or Northern America-Western European, with the exception of a study on game culture and players in the Middle East.

In quantitative studies, large-scale surveys are conducted and statistically analyzed. Bialas et al. (2014) examine the playstyles of users in eight different Western countries (Australia, Canada, Finland, Germany, the Netherlands, Sweden, the United Kingdom, and the United States) playing Battlefield 3 with statistical ANOVA tests. Ćwil and Howe (2020) combine statistical tests of chi-square, correlation, and MANOVA to identify differences of gamer identities between players in the USA and Poland. Researchers also designed itemized behavior measurements of video game players and test the measurements' validity among different cultures. Koban and Bowman (2020) utilize a five-factor Video Game Demand Scale (VGDS) to measure demands of video games players in Germany based on the results of measurements in the USA. Kahn et al. (2015) propose a new scale to examine player motivation of American and Chinese participants. Researchers have also investigated behavior focusing on online resources. Šisler et al. (2017) focus on user behavior through social networks, analyzing what fans liked on Facebook, based on an original method of Normalized Social Distance, calculating the distances between various social groups. Zagal and Tomuro (2013) compare Japanese and American user reviews by utilizing statistics and natural language processing. On the other hand, qualitative research investigated players' experiences more closely by analyzing player data through text analyses. For example, Brückner et al. (2019) utilize a Grounded Theory Approach to compare German and Japanese professional and user reviews to identify differences between German and Japanese player.

In terms of regions, cross-cultural research studies heavily involve participants in the USA and Germany, followed by other countries. As Šisler et al. (2017) mention, few research projects concentrate on studying game cultures in Eastern Europe or the Middle East. As such, many possibilities to comparative user studies across different cultures and regions are open and researchers should unite as well as systemize their methods to exhaustively define the differences and similarities among video game players.

Summary

Cross-cultural game studies aim to clarify and compare differences and similarities of games, game markets, game production and design, as well as the meaning and perception on games by game designers and players across two or more cultures on a regional or national level. Culture in game studies is understood as games as cultural artifacts or as parts of subcultures, consisting of a shared way of thinking, behavior, values, language, belief, and gaming practices among specific groups or individuals. Methods utilized in such cross-cultural studies include qualitative analyses of case studies, literature reviews,

interviews, and text analysis, as well as quantitative methods of surveys and statistical tests, network analysis, and natural language processing. Previous cross-cultural game studies mainly focus on the major fields of game markets, game production and design, game content, and player behavior as well as game and player interaction. However, more close analysis on granular fields is yet to be conducted, such as the game market of mobile games and application platforms, regulations, the role of game designers, game mechanisms, detailed analysis of game content, and player perception. Moreover, most studies have the tendency to compare the regions of the West and Asia or the USA and Japan to be in particular; however in this global era, where cultures diversely cross with one another, researchers should aim to study and compare regions on individual levels, to seek the transition and mixture of games and their surroundings. Such cross-cultural game studies lead to clarifying the changes of our contemporary understanding of culture in the globalized and digitized world.

Crowd Evacuation Simulation: Using simulation techniques to simulate the motion of crowds in evacuation in virtual environments.

Introduction

Crowd evacuation is important in building design, road infrastructure design, and city planning. A wide range of techniques have been proposed for crowd evacuation. The major aims of the studies on crowd evacuation include: (1) simulating the individual and crowd behaviors, (2) identifying the potential problems of building structures, (3) the effects of obstacles and exits, (4) optimal route computation. In an emergency evacuation, uncontrolled actions are observable in a massive crowd due to the influences of individuals. However, there are ethical issues to perform real life experiments. Therefore, using mathematical models and computer simulations are essential in studying crowd evacuation. The major goal of crowd evacuation simulation is that we would like to find the appropriate solutions to reduce fatality in emergency evacuation.

The organization of the rest of this chapter is as follows. In the beginning, we present crowd behavior analysis. Then crowd simulation techniques are presented, including microscopic, macroscopic, data-driven, and hybrid. After that we present the methods based on psychological factors and multi-cues. The crowd simulation techniques can be integrated into a crowd evacuation system to simulate the interaction among individuals and crowds. The following topics are route computation and crowd evacuation techniques. Finally, we conclude this chapter and highlight future research directions.

Crowd Behavior Analysis

Crowd behaviors (Sakour and Huosheng 2017) can be classified into three types: (1) individual, (2) interactions between individuals, and (3) crowd.

1. Individuals can make a good decision or bad decision in escaping from dangerous regions. They may be panic if the situation is out of control. Experienced individuals can calm down and help others.
2. Interactions between individuals: Inexperienced individuals may follow others even though the others may make a wrong decision. Panic individuals may need the help from others to calm down. Individuals may share ideas with each other to build up their own cognitive map.
3. Crowd: A crowd consists of individuals. Thus, a crowd may increase its density as more individuals join it. However, a higher risk level may be caused due to a degrading comfort level of the individuals.

A successful crowd evacuation technique should capture the essential behaviors of individuals and crowds. We can model crowds, groups, and individuals for scripted, reactive, and guided behaviors (Musse and Thalmann 2001).

Crowd Simulation

Crowd simulation techniques can be classified into macroscopic, microscopic, data-driven and hybrid.

Macroscopic Crowd Simulation

The macroscopic techniques focus on the aggregate behaviors of crowds, evaluation of building structures and performance. The computation cost is relatively lower than the microscopic techniques. In macroscopic crowd simulation, the individuals are grouped together. There are no interactions between individuals in the same group. The motion of pedestrians can be modeled as a kind of fluid.

We can derive a nonlinear, time-dependent equations for pedestrian flow based on three hypotheses (Hughes 2002) as follows:

1. *Hypothesis 1: The speed of pedestrians of a single type in multiple type flow is determined by the function f(ρ) but where ρ is the total density rather than the density of a single pedestrian type.*
2. *Hypothesis 2: A potential field exists for each pedestrian type such that pedestrians move at right angles to lines of constant potential.*
3. *Hypothesis 3: Pedestrians seek the path that minimizes their (estimated) travel time, but temper this behavior to avoid extremely high densities.*

The pedestrians are grouped into different types. Furthermore, The different groups make their way to one of a finite number of objectives. Let ρ_i be the density of pedestrians of particular type i. The total density is $\rho = \sum_{i=1}^{N} \rho_i$, where N is the number of pedestrian types. Then the flow of a particular type i of pedestrians is $\rho_i f_i(\rho)$, where $f_i(\rho)$ is a specified function of total pedestrian density for pedestrians of type i. Assume that φ_i is the potential for type i of pedestrians moving over the (x, y) floor plane. Denote $g(\rho)$ as the factor related to the discomfort of the crowd at a given density, and (x, y, t) denotes the horizontal space and time coordinates. For each type i of pedestrians, the governing equations are as follows:

$$-\frac{\partial \rho_i}{\partial t} + \frac{\partial}{\partial x}\left(\rho_i g(\rho) f_i^2 \frac{\partial \phi_i}{\partial x}\right) + \frac{\partial}{\partial x} \times \left(\rho_i g(\rho) f_i^2(\rho) \frac{\partial \phi_i}{\partial x}\right) = 0 \quad (1)$$

and

$$g(\rho) f_i(\rho) = \frac{1}{\sqrt{\left(\frac{\partial \phi_i}{\partial x}\right)^2 + \left(\frac{\partial \phi_i}{\partial y}\right)}}, i = 1, \cdots, N. \quad (2)$$

One possible choice for $f_i(\rho)$ is that $f_i(\rho)$ is linear in ρ, such as $f_i(\rho) = \beta_i(A - B\rho)$, $i = 1, \cdots, N$. Here, β_i, A, B should be selected appropriately.

A crowd of various types of pedestrians walk toward different objectives or with various speed relationships (Hughes 2003), which are not observed in a classical fluid. The shear force between the pedestrians and ground underneath should be considered.

Microscopic Crowd Simulation

In microscopic crowd simulation, a crowd is treated as a set of particles (or agents). Each agent has its own attributes, including position, velocity, destination, and psychological factors. Furthermore, agents can have interactions among each other. Although the computation cost is relatively higher than macroscopic techniques, the detailed simulation result can be achieved such as panicked individuals.

The simulation space for simulating crowd can be continuous or discrete. In a continuous space, the positions of agents are determined by their current positions and velocities. However, in a discrete space, the simulation space is discretized into a grid and the agents can move only to their neighboring cells. We give examples for these two simulation spaces as follows.

For a continuous space, the new position $\mathbf{p}(t + \Delta t)$ of an agent is updated based on its current position $\mathbf{p}(t)$, velocity $\mathbf{v}(t)$, and time step size Δt, i.e.,

$$\mathbf{p}(t+\Delta t) = \mathbf{p}(t) + \mathbf{v}(t)\Delta t, \tag{3}$$

where t is the current time. The velocity of the agent is affected by factors such as the velocities of neighboring agents, crowd density, and obstacles.

For a discrete space, an agent can jump to a position of a set of fixed positions. Cellular automata are a popular class of discrete models. In a cellular automaton model, it has a grid of regular cells and there is at most one agent at a grid cell at a time. An agent can move from its current grid cell to a neighboring grid cell within a simulation step. Thus, for a regular grid with square cells, there are at most eight neighboring cells for one grid cell.

Discrete Techniques. We use a theatre to illustrate this kind of techniques. The space of the theatre is discretized as a regular grid with square cells. We can construct a floor field by assigning higher probability to aisle regions than seat regions in a theatre (Yang et al. 2010). At an exit area, an information board shows the real time information (e.g., exit density) to the agents to aid them make movement decision. A grid cell dimension is 0.5 m × 0.5 m and it has a total attraction value which is used for computing a probability of an agent to move to it. An agent has a higher chance to move to a neighboring cell with higher total attractive value. The total attraction value of a cell (i, j) is computed as

$$N_{ij} = e^{k_s \times (S_1 + S_2) + k_r \times R + k_d \times D}, \tag{4}$$

where S_1 is the attraction of exit position, S_2 is the attraction of aisle region; R is the repulsive force between agents or between agents and obstacles; D is the influence factor of neighboring agents (due to psychology); k_s, k_d, k_d are the weights for setting the dominant roles of the parameters. R is a non-positive value and D is a non-negative value. Thus, R and D play a negative and positive effect for choosing the cell, respectively. The transition probability to cell (i, j) is

$$p_{ij} = \frac{N_{ij}}{\sum_{(k,\ell)\in G(i,j)} N_{k\ell} \times (1 - n_{k\ell}) \times w_{k\ell}}, \tag{5}$$

where $G(i, j)$ is the set of neighboring cells of (i, j); $n_{k\ell}$ and $w_{k\ell}$ indicate whether the grid cell (k, ℓ) is occupied or there is an obstacle, respectively.

We can combine cellular automata with game theory to perform crowd evacuation (Zheng and Cheng 2011). The main idea is to apply game theory for determining the movement directions of agents. The agents may consider to cooperate or adopt a competitive manner while they evacuate. The following three results are obtained:

1. A longer evacuation time is required and also the frequency of cooperation reduces for higher degree of emergency.
2. Hyper-rationality inhibits cooperation and delays evacuation times, which may lead to crowd disaster.
3. The frequency of cooperation increases for higher degree of imitation among evacuees but also leads to longer evacuation times.

Continuous Techniques. Helbing and Molnar (1995) proposed a force-based model to simulate the behaviors of pedestrians. The surrounding environment and agents exert forces on an agent. The main idea is to compute the total force on an agent. The forces should be considered as influences of the surrounding objects to the agent. We consider that the net force exerting on an agent is **f**. Then the velocity is updated as

$$\mathbf{v}(t+\Delta t) = \mathbf{v} + \frac{\mathbf{f}}{m}\Delta t, \tag{6}$$

where m is the mass of the agent. To determine the velocities of the agents, we can also compute feasible movement directions of agents based on reciprocal velocity obstacles (Van den Berg et al. 2008). The possible movement direction of an agent is computed based on the positions and velocities of the other agents. The feasible direction is picked for avoiding collisions. Furthermore, a collision prediction scheme can be performed to evaluate the possible future collisions of each agent (Karamouzas et al. 2009). Each agent adapts a new route as early as possible in order to minimize the influence of others. In

general, the agent avoids collision with another agent if they may collide in the earliest contact time. The result indicates that the approach leads to shorter and less curved paths.

To achieve biomechanically energy-efficient and collision-free trajectory, we can apply the principle of the least effort to determine the velocities of the agents (Guy et al. 2010). The instantaneous power (P) spent by a walking agent is computed as

$$P = e_s + e_w \|\mathbf{v}\|^2, \tag{7}$$

where $\mathbf{v}$ is the instantaneous velocity, and e_s (measured in *J/Kg/s*) and e_w (measured in *Js/Kg/m*^{2}) are constant. Assume that the mass of the agent is m. The total consumed metabolic energy of the agent while walking along a path is computed as

$$E = m \int \left(e_s + e_w \|\mathbf{v}\|^2 \right) dt. \tag{8}$$

The function E is the subject to be minimized to obtain the path of the agent.

To implement the concept about "right of way," we can assign agents of different priorities (Curtis et al. 2013). The agents with lower priority give way to those with higher priority. This is crucial at narrow regions. If there is no "right of way" mechanism, the agents may block at a narrow passage.

It is efficient to compute the local views of agents to determine the movement of the agents (Fu-Shun Li and Sai-Keung Wong 2016). Each agent has the local view of its neighborhood region and it picks the feasible direction that costs the least effort in term of the turning direction of the agent. Furthermore, the speed of agents is also affected by the local density. For higher crowd density, the speed of an agent is slower. Conversely, if the crowd density is low, the agent can move at its desired speed. The agents can also follow some guidance paths to move. A navigation field can be constructed based on the guidance paths. Each cell of the navigation field has a movement direction and the agent at that cell follows the direction to move. The navigation field can guide a large amount of agents to move to a common destination (Tsung-Yu Tsai et al. 2017). However, if the guidance paths intersect with each other or congestion occurs, we can adjust them by applying particle swarm optimization to achieve better traveling time of the agents (Wong et al. 2015). A fitness function is used to evaluate the quality of the guidance paths. The fitness function for a finite generation period is constructed as follows. All the agents should move to their destinations before the simulation process is terminated. Let $\widehat{N}_G$ be the number of agents not reaching the destination before the simulation is finished. Denote a particle position $\mathbf{x}$ (i.e., a guidance path). Then the fitness function is as follows:

$$F_1(\mathbf{x}) = B\left(\widehat{N}_G\right) * \left(\overline{T} + \alpha \overline{S}\right), \tag{9}$$

where $\overline{S} = \frac{\overline{\ell}}{\overline{s}} \frac{\overline{T}}{\Delta t}$, $\overline{T}$ is the average traveling time, $\overline{\ell}$ is the average interaction distance of agents, $\overline{s}$ is the average desired speed of agents, and α is a constant. $\overline{S}$ is the average extra traveling time for all agents. We would like to adjust the guidance path so that all the agents should reach the destination. Therefore, we set $B\left(\widehat{N}_G\right) = 1$ for $\widehat{N}_G = 0$; and $B\left(\widehat{N}_G\right) = 1 + \widehat{N}_G$ for $\widehat{N}_G \geq 1$. The term $\frac{\overline{\ell}}{\overline{s}}$ represents the extra average traveling time of agents per simulation time step due to collision resolution for agents. The term $\frac{\overline{T}}{\Delta t}$ is the average simulation time steps for agents to move to their destinations. The guidance paths are adjusted iteratively until the fitness value reaches a minimum value (Wong et al. 2015).

Data-Driven and Hybrid Techniques

To calibrate crowd models and group models (Kang Hoon Lee et al. 2007), we can adopt the evolutionary optimization to compute parameters from real videos (Johansson et al. 2007). To achieve better calibration results, we can classify the types of crowd based on steering contexts (e.g., groups crossing and chaos) (Boatright et al. 2015). In this way, we can capture the main characteristics of crowds in each steering context. Based on the characteristics of a steering context for a crowd, the best crowd-simulation technique

can be employed to simulate the crowd. Furthermore, we can measure the density of a crowd to evaluate the similarity between simulation results and real crowd motion in videos (Lerner et al. 2009). The density measure takes into account the local crowd densities surrounding a subject agent. Based on the density measure, we can compute similarity scores for the simulation results and then adjust the calibrated parameters.

Psychological and Multi-Cue Methods

To achieve realistic simulation of high-density crowd, we should combine physical force; agent personalities; and psychological, physiological, and geometrical rules to simulate the local motion of autonomous agents (Pelechano et al. 2007). Furthermore, to handle a large amount of heterogenous agents, we can adopt a multi-agent paradigm in a distributed simulator (Dimakis et al. 2009). Psychological parameters in crowd models make crowds exhibit various personalities and emotions (Durupınar et al. 2016). A virtual agent consists of features that determine cognitive, perceptual, and psychological characteristics. The agents react according to the interaction between the features and environment stimuli. We can integrate different cues including sound perception, multi-sense attention, and understanding of environment semantics, to enhance the realism of crowd (Kapadia et al. 2015).

Evacuation Route Computation

There are mathematical models to compute optimal routes (Hamacher and Tjandra 2002). An environment is represented as a graph which consists of a set of nodes and a set of edges. The nodes and edges are the intersections and roads of the environment. The models require the input of the movement speed of a crowd and road capacities.

To evaluate whether a building is well designed, we can compute the travel time of a crowd (Thompson and Marchant 1995). The quality of an exit assigned to an agent can be evaluated based on earliest arrival flows, maximum flows, and minimum cost flows (Dressler et al. 2010). To make the problem tractable, the methods based on cellular automata can be adopted. Furthermore, controlled dynamic exit signs can be employed for evacuation routes (Desmet and Gelenbe 2014). To compute evacuation routes for three-dimensional networks, we can employ the pseudo-polynomial-time dynamic programming algorithm (Tang et al. 2014).

For evenly distributed agents in an area, we can compute evacuation routes by using the genetic algorithm (Abdelghany et al. 2014). Furthermore, we can apply an evolutionary algorithm to compute the best region assignment that describes how agents in regions are assigned to exits of a building or an open area (Jinghui Zhong et al. 2015). A particle encodes the region assignment and the subregions are encoded as chromes. Mutation and crossover are performed to update the particles based on the result obtained from a cellular automata-based simulation.

An alternative way to compute evacuation routes is to apply agent-based simulation. It is applicable to an environment which can be represented as a road network and a set of obstacles (Sai-Keung Wong et al. 2016, 2017). Agents move along the roads. Along each road, there is a division point which divides the agents on the road into two groups moving in the opposite directions. If the agents move to a junction, they are split into smaller groups and move along the subsequent road segments. The approach computes the division points such that the agents around the division points have similar average evacuation times.

Crowd Evacuation and Building Design

There are a variety of concerns for crowd evacuation. There can be agents of different kinds, such as children, parent, and authorities (Tsai et al. 2011). It is shown that it is effective for a few leaders guiding evacuees to safety regions (Pelechano and Badler 2006). There may be a negative impact if there were too many leaders (Yi Ma et al. 2016). Furthermore, the evacuation strategies should depend on the types of interaction, grouping restrictions, and environment factors (e.g., hazardous areas) (Rodriguez and Amato 2010). Members of the same group should remain

within a predefined distance of others. The members can help each other. Agents may have various degree of knowledge about the environment.

We can adopt appropriate methods to perform evacuation. To perform evacuation in buildings caused by fire, we can adopt dynamic network flows (Hadzic et al. 2011). Regions which are not reachable are removed from the graph. The effects of temperature, spread of smoke speed, and CO (carbon oxide) in fire scenes should also evaluated (Hai-Rong Wang et al. 2014). People should avoid congestion and move to large space. Furthermore, due to guidance signs, people may move together. Thus the movement speed should be carefully monitored to avoid congestion.

To guide the design of a building, we can evaluate the effects of the placement of pillars and doors (Berseth et al. 2015). Let **p** be the set of parameters of a scene configuration. A crowd flow for a specific scenario with parameterization **p** is defined as

$$f(\mathbf{p}) = \frac{|A_c|}{t_{avg}}, \tag{10}$$

where, $t_{avg} = \frac{\sum_{a \in A} t_a}{|A|}$, $|A_c|$ is the destination, t_a is the time taken by agent a to reach the destination, t_{avg} is the average completion time of agents, $|A|$ is the cardinality of set A. The goal of the study was to find **p** which minimizes $f(\mathbf{p})$. The local navigation abilities of the agents affected the results for different kinds of steering techniques. Hence, evacuation techniques based on statistical analysis are highly demanded. Bidirectional traffic patterns are greatly affected by door widths.

Summary

This chapter covers a variety of simulation techniques for crowd evacuation. There are two categories of crowd simulation: macroscopic and microscopic. Macroscopic-based techniques are useful in computing the global behaviors of crowds. To model the individual behaviors and interactions between individuals, microscopic-based techniques should be employed. Hybrid-based techniques are devised from the microscopic and macroscopic techniques. Data-driven techniques can be employed to calibrate the parameters of various crowd-simulation techniques. Route-computation techniques are also crucial. The best routes can be transmitted to devices of people via wireless communication, such as mobile phones (Inoue et al. 2008).

It would be compelling to improve the overall coordination opportunity and evacuation result via cooperation of individuals. Efficient and accurate prediction methods should be developed to prevent disaster from occurring. Due to ethical issues, Sadiyoko et al. (2012) modeled the psychological behaviors of human based on a psychological dynamic model in order to understand how people interact with each other. The models of psychological behaviors can be applied to robots. For example, the emergence of chaos observed in a simulation result of robots can be useful in predicting when a real crowd will occur with the same chaos. Consequently, the chaos for human could be avoided.

Crowd animation

Definition

Process of simulating the movement and/or the behavior of a large number of entities or characters.

Introduction

Computer-generated crowds of virtual humans gain a lot of attention these years. Applications are multiple. Accurate crowd simulation is required for risks and evacuations planning. The entertainment industry is demanding of realistic-looking crowd of virtual characters in order to create amazing scenes in movies, commercials, or video games. Believable virtual crowds are the key of success for virtual therapies treating agoraphobia. Real-time 3D crowds could populate virtual cities and virtual worlds can be found on the Internet.

Realistic-looking, believable-behaving, and real-time rendered virtual crowds are challenging. At the individual scale, virtual agent must look realistic, i.e., the 3D models are textured and lighted. They are goal-directed behaving. People don't walk in the streets freely, i.e., going in a random direction each time they encounter an obstacle. Usually they walk with a goal in mind: going to work, shopping. At the crowd level, each virtual character should be unique. Except if you are surrounded by pairs of twins dressed similarly, in real life everybody has different morphology and clothes. Crowd dynamics should be respected. Virtual characters avoid each other to not collide. Flows are created naturally in a dense crowd. Another important aspect of crowd is the number of virtual characters. One can start speaking of crowd if at least one hundred agents are rendered. Massive crowds can count several thousands of characters. Real time adds the constraint that virtual characters are simulated, animated, and rendered at frame rates that allow user interactions.

Most approaches are application specific, focusing on different aspects of the collective behavior, using different modeling techniques. Employed techniques range from those that do not distinguish individuals such as flow and network models in some of the evacuation simulations, to those that represent each individual as being controlled by more or less complex rules based on physical laws, chaos equations, or behavioral models in training systems or sociological simulations.

Historic Background

Human beings are arguably the most complex known creatures; therefore, they are also the most complex creatures to simulate. A behavioral animation of human (and humanoid) crowds is based on foundations of group

simulations of much more simple entities, notably flocks of birds (Reynolds 1987) and schools of fish (Tu and Terzopoulos 1994). The first procedural animation of flocks of virtual birds was shown in the movie by Amkraut, Girard, and Karl called *Eurhythmy*, for which the first concept was presented at the Electronic Theater at SIGGRAPH in 1985. In his pioneer work, Reynolds (1987) described distributed behavioral model for simulating aggregate motion of a flock of birds. Brogan and Hodgins (1997) simulated group behaviors for systems with significant dynamics. Bouvier and Guilloteau (1996) presented a crowd simulation in immersive space management and a new approach of particle systems as a generic model for simulations of dynamic systems. Musse and Thalmann (2001) presented a hierarchical model for real-time simulation of virtual human crowds. Their model is based on groups, instead of individuals: groups are more intelligent structures, where individuals follow the groups' specification. Groups can be controlled with different levels of autonomy: guided crowds follow orders given by the user in runtime; programmed crowds follow a scripted behavior; and autonomous crowds use events and reactions to create more complex behaviors. O'Sullivan et al. (2002) described a simulation of crowds and groups with level of details for geometry, motion, and behavior. Decision systems are generally applied to simple reactive behaviors such as collision avoidance because of the computational cost of implementing existing rational models with a crowd of virtual people.

Variety

To generate thousands of individuals, a naive approach is to design as many humans as there are people in the crowd. Obviously, such an approach is impossible, since it would require armies of designers and an infinite memory. The common and more reasonable approach is to use human templates. A human template is a virtual human defined by its skeleton, its mesh, which is skinned to the skeleton, and its set of textures. To create large crowds, a small group of human templates are instantiated several times. For each instance, one texture is randomly chosen within the template's available set. Then, color and shape variety techniques are applied so that instances of a same template and using the same texture are still different.

Previous work on color variety is based on the idea of dividing a human template into several body parts, identified by specific intensities in the alpha channel of the template texture. At runtime, each body part of each character is assigned a color in order to modulate the texture. Although these methods offer nice results from a reasonable distance, they produce sharp transitions between body parts.

For large crowds, a common approach consists in modifying separately the height of the human body and its shape. The height of a human template can be modified by scaling its skeleton (Fig. 1). For each new skeleton, a global scale factor is randomly chosen within the given range. Then, the associated new scale for each of its bones is deduced. Short/tall skeletons mixed with broad/narrow shoulders are thus created. The skin of the various skeletons also needs adaptation. Each vertex of the original template is displaced by each joint that influences it.

Crowd Simulation, Fig. 1 Changing the height

For the shape, the human mesh is modified using three steps: (1) An area called FatMap (see Fig. 2) is automatically painted on each individual; when the creation of the FatMap is complete, the grayscale values at each texel are used to automatically infer one value for each vertex of the template's mesh. Each of these values, called a fatWeight, is attached to the vertex as an additional attribute. (2) It is computed in the direction the vertices are moved when scaled; for this, we compute the scaling direction of each vertex as the weighted normal of the bones influencing it. (3) Once the direction of the body scaling is computed for each vertex, the actual scaling can take place. The extent to which we scale the body is defined by a fatScale, randomly chosen within a predefined range.

Crowd Simulation, Fig. 2 FatMaps – *Dark* areas represent regions more influenced by fat or muscles modification, while *lighter* parts are less modified

Accessories

Accessorizing crowds offers a simple and efficient alternative to costly human template modeling. Accessories are small meshes representing elements that can easily be added to the human template original mesh. Their range is considerable, from subtle details, like watches, jewelry, or glasses, to larger items, such as hats, wigs, or backpacks, as illustrated in Fig. 3. Distributing accessories to a large crowd of a few human templates varies the shape of each instance and thus makes it unique. We can distinguish three types of accessories.

Crowd Simulation, Fig. 3 Population with accessories: bags, hats, glasses

The first group of accessories does not necessitate any particular modification of the animation clips played. They simply need to be correctly "placed" on a virtual human. Each accessory can be represented as a simple mesh, independent from any virtual human. First, let us lay the problem for a single character. The issue is to render the accessory at the correct position and orientation, accordingly to the movements of the character.

The second group of accessories we have identified is the one that requires slight modifications of the animation sequences played, e.g., the hand close to the ear to make a phone call or a hindered arm sway due to carrying a heavy bag. Concerning the rendering of the accessory, we still keep the idea of attaching it to a specific joint of the virtual human. The additional difficulty is the modification of the animation clips to make the action realistic. If we want a virtual human to carry a bag for instance, the animation modifications are limited to the arm sway and maybe a slight bend of the spine to counterweight the bag. If it is a cell phone accessory that we want to add, we need to keep the hand of the character close to its ear and avoid any collision over the whole locomotion cycle.

The third category of accessories is the one which needs a specific animation; we can consider in this category handicapped people using crutches, skating, and scooter. We may consider accessories that have their motion but linked to the motion of the pedestrian like: a wheelbarrow, a caddy. Accessories may also have their own animation like a dog with a lash. Another category of accessories are the ones requiring more than one person to carry them, for example, furniture.

Figure 3 shows examples of accessories.

Animation Variety

A second important factor, although less paramount is their animation. If they all perform the same animation, the results are not realistic enough. We can consider three techniques to vary the animation of characters while remaining in the domain of navigating crowds, i.e., working with locomotion animations:

1. Variety can be introduced in the animation by generating a large amount of locomotion cycles (walking and running) and idle cycles (like standing, talking, sitting, etc.) that we morphologically adapt for each template. For locomotion clips, walk and run cycles can be generated from a locomotion engine based on motion capture data.
2. Precomputed animation cycles can be augmented with upper body variations, like having a hand on the hip or in a pocket.
3. Finally, procedural modifications can be applied at runtime on locomotion animations to allow crowds to wear complex accessories as mentioned earlier.

The principal component analysis (PCA) method is often used to represent the motion capture data in a new, smaller space. As the first PCs (principal components) contain the most variance of the data, an original methodology is used to extract essential parameters of a motion. This method decomposes the PCA in a hierarchical structure of sub-PCA spaces. At each level of the hierarchy, an important parameter of a motion is extracted and a related function is elaborated, allowing not only motion interpolation but also extrapolation. Figure 4 shows an example of PCA-based locomotion.

Path Planning and Navigation

Path planning is an important and challenging task in crowd simulation, which helps each agent to find the path to its individual goal. The path planning problem has been widely explored by the robotics community. Although the multiple-agent path planning has been addressed for cooperative tasks of multiple robots, it is still a challenge to solve the path planning problem for large crowds in real time, especially for large-scale crowds. Because the methods used for robots are usually exponential in the number of robots,

Crowd Simulation, Fig. 4 PCA-based walking models

which are too expensive to be adopted in crowd simulation.

Four types of methods are popular for path planning and navigation:

1. **Social force models**. Helbing's social force model (Helbing et al. 2000) is one of the most influential models in agent-based motion planning. This model considers each agent as a particle subject to long-ranged forces induced by the social behavior of individuals. The movement of agents can be described with a main function which determines the physical and social forces, similar to Newtonian mechanics. The social force model is capable of describing the self-organization of several observed collective effects of pedestrian behavior.
2. **Probabilistic roadmaps**. Benefiting from motion planning algorithms in robotics, geometric representation of probabilistic roadmaps (PRM) can also be used for path planning in crowd simulation. PRM was applied to solve the problem of determining a collision-free path between a starting configuration of the robot and a goal configuration.
3. **Visibility graphs**. A visibility graph is used for the path planning for large numbers of virtual agents. The visibility graph connects together vertices of the environment if and only if they see each other. Inspired from Voronoi diagrams, Pettré et al. (2006) presented a novel approach to automatically extract a topology from a scene geometry and handle path planning using a navigation graph. The environment is usually discretized into a fine regular grid in the potential field method.
4. **Potential fields**. The method (e.g., Treuille et al. 2006) produces a potential field from the addition of a static field (goal) and a dynamic field (modeling other people). Each pedestrian then moves against the gradient towards the next suitable position in space (a waypoint) and thus avoids all obstacles.

Collision Avoidance

Except the topological model of the environment and path planning, collision avoidance is another challenging problem to be addressed. The collision avoidance techniques should be efficient enough to prevent a large number of agents from bumping into each other in real time. The greatest difficulty of collision avoidance is from the absence of other agents' current velocities. Furthermore, the agents are not able to communicate to coordinate their navigation. A common solution to this problem is to assume that the other agents are dynamic obstacles whose future

motions are predicted as linear extrapolations of their current velocities. The agent then selects a velocity that avoids collisions with the extrapolated trajectories of other agents. This is the idea of velocity obstacle. Considering the case in which each agent navigates independently without explicit communication with other agents, van den Berg et al. (2008) propose a new concept, the "reciprocal velocity obstacle," which takes into account the reactive behavior of the other agents by implicitly assuming that the other agents make a similar collision avoidance reasoning. This concept can be applied to navigation of hundreds of agents in densely populated environments containing both static and moving obstacles for real-time simulation.

Crowd Behavior

The behavior of people in a crowd is a fascinating subject: crowds can be very calm but also rise to frenzy; they can lead to joy but also to sorrow. It is quite a common idea that people not only behave differently in crowd situations but that they undergo some temporary personality change when they form part of a crowd. Most writers in the field of mass- or crowd psychology agree that the most discriminating property of crowd situations is that normal cultural rules, norms, and organization forms cease to be applicable. For instance, in a panic situation the normal rule of waiting for your turn and the concomitant organization form of the queue are violated and thus become obsolete.

A simple method for describing the crowd behavior is through group interrelationships. Virtual actors only react in the presence of others, e.g., they meet another virtual human, evaluate their own emotional parameters with those of the other one, and, if they are similar, they may walk together. The group parameters are specified by defining the goals (specific positions which each group must reach), number of autonomous virtual humans in the group, and the level of dominance from each group. This is followed by the creation of virtual humans based on the groups' behavior information. The sociological effects modeled in the presented rules are:

- *Grouping* of individuals depending on their interrelationships and the domination effect
- *Polarization and the sharing effects* as the influence of the emotional status and domination parameters
- *Relationship* between autonomous virtual humans and groups

Environment modeling is closely related to behavioral animation. The purpose of the models of the environment is to facilitate simulation of entities dwelling in their surrounding environments. Believability of virtual creatures can be greatly enhanced if they behave in accordance with their surroundings. To make crowd movements more realistic, the first important step is to identify the main places where many people tend to go, i.e., places where there is a lot of pedestrian traffic. It can be a shopping mall, a park, a circus, etc. Adding meta-information to key places in an environment has been achieved in many different ways.

A recent effort in improving the crowd behavior has been focused on creating groups. In our everyday life, it is rare to observe people in an urban scene walking all by themselves. Indeed, it is easy to notice that pedestrians often evolve in groups of two or more. For this reason, we introduce an additional and optional layer to our motion planning architecture. This layer takes care of creating small groups of people, which try to remain close to each other during simulation. Figure 5 shows an example of crowd.

Crowd Simulation, What's Next

Crowd simulation is generally seen as the process of simulating the movement of a large number of entities or characters, and key issues seem to be path planning and collisions. But huge crowds generally don't walk; 90 % of crowd images on

Crowd Simulation, Fig. 5 Crowd simulation

Google Images show static crowds. Crowds are not only moving, and even when they move, they can run or even swim in a crowded pool. Most path planning algorithms for walking won't work for swimming.

A lot of research has focused on the collective social behavior of people at social gatherings, assemblies, protests, rebellions, concerts, sporting events, and religious ceremonies, but there are very few simulations showing such case studies.

Behaviors are very situation dependent; for example, people in a city generally walk and stop only to watch events or chat with people. Many people in public parks will sit down in the grass or on public seats.

In terms of appearance, research has focused on shape, size, skin color, and accessories. But, we should see more by representing children, babies, old people, and handicapped people. We should also mix people with cars, bicycles, etc.

Currently, individuals in crowds can carry accessories; what we don't see is crowds manipulating objects, open doors, eating, bringing objects from one place to another, and exchanging objects.

There are other scenes we did not see until now in simulations like large restaurants or crowded buses.

Most crowds are composed of people with a goal; but on a Sunday afternoon, many people wander without specific goals.

Natural motivations should be introduced to simulate more complex and realistic situations. For example, in an airport, people should not just check in, go to the security, then the gate, as in most simulations. They should be able to go to restaurants, cafés, shops, and toilets according to their internal motivations. Such models exist for individuals or small groups, but the problem is that it will be extremely CPU intensive to introduce them to large crowds. More details may be found in (Thalmann and Musse 2012).

Definitions

Cybersickness is an uncomfortable side effect experienced by users of immersive interfaces commonly used for Virtual Reality. It is associated with symptoms such as nausea, postural instability, disorientation, headaches, eye-strain, and tiredness.

Cybersickness

Cybersickness is a relatively common, unwanted side effect of immersive interfaces that causes a broad range of unpleasant symptoms such as nausea, headaches, disorientation, and tiredness. More serious symptoms, such as postural instability, although less common, can also result from prolonged exposure to virtual interfaces.

Cybersickness is typically experienced by stationary users that perceive that they are moving in a virtual scene. This stationary reality and the associated compelling experience of self-motion is believed to underlie the condition (Webb and Griffin 2003). By contrast, simulator sickness was first found in pilots who underwent extended training in flight simulators that tried to provide a real sense of vehicle movement using motion platforms (Kennedy et al. 1993). It is likely that there are discrepancies between the simulator's actual motion and the expected motion of the virtual vehicle that contribute to simulator sickness.

Cybersickness and simulator sickness share similar symptoms with motion sickness although the conditions are caused by exposure to slightly different situations. Younger children, aged between 4 and 12, are more prone to motion sickness and indeed susceptibility to this condition in childhood can be a good indicator of susceptibility to cybersickness (Golding 1998). Motion sickness can be brought on by travelling in any type of moving vehicle including cars, buses, trains, aircraft, boats, and submarines and may also be induced on an amusement ride, a spinning chair or simply by using a swing at a playground. Astronauts may experience a related form of motion sickness, called "space adaptation syndrome" that occurs in exposure to zero-gravity conditions (Davis et al. 2015).

While there are definite relationships between the symptoms experienced in cybersickness, simulator sickness, and motion sickness, they may provoke slightly different clusters of symptoms that can help differentiate the three conditions (Kennedy et al. 1993). In one of the largest early studies of symptoms, available data from 10 United States Navy flight simulators, using 1,119 pairs of preexposure and postexposure scores from self-reported data on motion sickness symptoms, were analyzed using a series of factor analyses to identify 16 principal symptoms clustered into the three main categories of oculomotor, disorientation, and nausea (Kennedy et al. 1993). The oculomotor cluster includes the symptoms of eyestrain, difficulty focusing, blurred vision, and headache (Kennedy et al. 1993). The disorientation cluster includes dizziness and vertigo, while the nausea cluster includes stomach awareness, increased salivation, and burping (Kennedy et al. 1993). A further dimension of cybersickness related to the "sopite syndrome" has also been characterized, and this includes symptoms of drowsiness, yawning, disengagement, and negative affect (Lawson and Mead 1998).

The actual cause of cybersickness is not known and the underlying physiological mechanisms are uncertain. The three most prominent theories for the cause of cybersickness are postural instability theory, poison theory, and sensory conflict theory (LaViola 2000).

The postural instability theory is based on the idea that the main goal of humans is to maintain postural stability in the environment (Riccio and Thomas 1991). Therefore, prolonged postural instability results in cybersickness symptoms and the longer the instability, the more severe the symptoms are likely to be (LaViola 2000). By contrast, poison theory suggests an evolutionary survival mechanism comes in to play when the user experiences sensory hallucinations consistent with ingesting some type of poison (Bouchard et al. 2011). It is suggested that patterns of visual and vestibular stimuli may trigger motion

sickness by accidentally activating brain sensors for detecting toxins (Treisman 1997).

However, the most longstanding and popular explanation for cybersickness is known as the sensory conflict theory (Cobb et al. 1999; Kolasinski 1995; LaViola 2000). This theory describes the conflicts of two key sensory systems engaged in virtual environments, namely, the visual and vestibular senses (Kolasinski 1995). They provide information about an individual's orientation and perceived motion, and it is the mismatch of these senses that can frequently occur in Virtual Reality. For example, the vestibular system may be telling the individual that their body is stationary, while the visual system is telling them that their body is moving, causing a sensory mismatch (Howarth and Costello 1997). Unfortunately, like the other theories, the sensory conflict theory lacks predictive power in determining how severe the symptoms of cybersickness will be relative to any virtual experience. Furthermore, these various theories still fail to explain why, given identical virtual experiences, some individuals get sick and others do not.

While the underlying mechanisms that cause cybersickness are still not completely understood, there has been more success in identifying some of the factors known to impact on users developing symptoms. These factors are varied and relate to individual differences, variations in the devices being used, the task being performed, and the design of the virtual environment.

Individual factors that impact on cybersickness include age, gender, race, illness, and posture. Children in the 2–12 age range have the greatest susceptibility to cybersickness, and this rapidly decreases from the ages of 12–21 and beyond (Kolasinski 1995). Thus, older people are less susceptible to symptoms. In relation to gender, women have a wider field of view which increases the likelihood of flicker perception and this in turn increases their susceptibility to cybersickness (LaViola 2000). Research has also shown that female hormones can affect susceptibility (Kolasinski 1995). For all users, any underlying illness increases an individual's susceptibility to cybersickness. These physical conditions include, but are not limited to, fatigue, hangovers, and the flu (LaViola 2000).

The ranges of device factors that impact on cybersickness are lag, flicker, calibration, field of view, and general ergonomics. One problem with most stereoscopic displays is known as accommodation-convergence conflict (Durlach and Mavor 1994). In the real world, our eyes converge to look at near objects while also focusing (accommodating) at the same distance on the object. However, in Virtual Reality, while the eyes will still converge to look at a virtual object, the focus needs to be on the plane of the display itself rather than the object. Other characteristics of head-mounted displays that may be relevant are the vertical and horizontal field of view, the resolution, the contrast, the luminance, and color characteristics of the display (Durlach and Mavor 1994).

The refresh rate of the display can also be important factor as any lag in the system can contribute to cybersickness symptoms (LaViola 2000). Lag occurs when there is a delay between an individual's action (e.g., turning a steering wheel) and the system's reaction. Real time graphical displays that can operate at around 50–60 Hz are critical. Efficient tracking of head movements is also critical as people expect their view to change promptly when they move their head. Any errors in accuracy of tracking of head movement can likewise impact on cybersickness. Display flicker, a visible fading between video frames, is also related to visual refresh rate. Flicker is not only distracting but also causes eye fatigue (Kolasinski 1995). Flicker fusion is an important property of the device and is even more critical for wider fields of view as peripheral vision is more sensitive to flicker (LaViola 2000). The perception of flicker is another factor that can also vary between individuals.

Due to differences in physical characteristics, poor system calibration can also increase cybersickness symptoms. For example, interpupillary distance, which is the distance between the centers of the pupils of both eyes, varies between individuals (Kolasinski 1995). As stereoscopic displays require each eye to receive a slightly offset view

of the virtual world, this offset needs to correspond as closely as possible to the users own specific interpupillary distance. As such appropriate calibration is required for each individual. General ergonomic factors also need to be considered when designing immersive systems. For example, heavy and poor fitting headsets can cause physical discomfort, and restricted movement from cables can cause further distractions from the virtual experience (McCauley and Sharkey 1992). Furthermore, head-mounted displays impact on the normal inertia characteristics of the head, generating unusual forces during head movements that can also directly impact on cybersickness (Durlach and Mavor 1994). The posture of the individual, possibly related to the postural instability theory, is also important. For example, sitting is a safer posture for users than standing as this reduces any demand on postural control (Kolasinski 1995).

Cybersickness can also be influenced by the specific task the user is performing in the environment. The main task factors include the level of control the user has and the duration of the task. Participants who have good control in a virtual environment can better predict future motion and are found to be less susceptible to cybersickness. By contrast, users with no control over the virtual environment lack the same level of predictability about the environment and are thus more prone to symptoms (Kolasinski 1995). Longer exposure times to Virtual Reality also increase the likelihood and severity of cybersickness and lead to the need for longer adaptation periods. Indeed, using brief exposures to virtual environments is one way to improve the speed of adaptation (Kolasinski 1995; McCauley and Sharkey 1992).

As the illusion of motion is one of the factors that induce cybersickness, the design of the virtual world, in terms of visual complexity and amount of motion associated with the visual stimuli, is also an important factor that might be controlled (So et al. 2001). For example, during the design of virtual experiences, optical flow might be used as a measure the complexity of motion in a stream of video frames (Ali 2013; Beauchemin and Barron 1995). Likewise, a measure such as approximate entropy can be used to provide a general understanding of the complexity of changing scenes in a virtual environment (Smith et al. 2017).

As it stands, cybersickness still provides an obstacle to the wide spread adoption and commercial development of technologies associated with Virtual Reality. Of particular advantage would be better quantitative measures for predicting a user's susceptibility to cybersickness and reliable methods for detecting and measuring symptoms such as the nausea associated with the condition. Most historical studies of cybersickness have relied on subjective self-reporting of the severity of symptom conditions (Ames et al. 2005; Cobb et al. 1999; Dennison et al. 2016; Gianaros et al. 2001; Golding 1998; Kennedy et al. 1993; Nesbitt et al. 2017).

The Pensacola Motion Sickness Questionnaire (Kellogg et al. 1965) based on 27 previously identified issues (Hardacre and Kennedy 1963) is recognized as one of the earliest subjective measures designed for assessing motion sickness (Bouchard et al. 2011). This work led to the development of the Pensacola Diagnostic Index (Graybiel et al. 1968). The Pensacola Diagnostic Index score is calculated by summing an individual's ratings on various scales related to the symptoms of dizziness, headache, warmth, sweating, drowsiness, salivation, and nausea. After a major study analyzing the factors relevant to simulator sickness, an alternative 16-item Simulator Sickness Questionnaire was developed (Kennedy et al. 1992). Another widely used survey instrument is the Nausea Profile (Muth et al. 1996). Like the Simulator Sickness Questionnaire, the Nausea Profile is distinguished from approaches such as the Pensacola Diagnostic Index in that it examines symptoms along multiple dimensions. Another multivariate questionnaire was developed to measure the symptoms associated with the subscales of gastrointestinal, central, peripheral, and sopite-related symptoms (Gianaros et al. 2001). More recently, the Virtual Reality Symptom Questionnaire (Ames et al. 2005) was developed specifically for investigating symptoms that result from Virtual Reality viewing using technology such as head-mounted displays.

Generally, subjective approaches for measuring cybersickness symptoms elicit an individual's ratings on scales that relate to either the propensity to be susceptible to simulator, motion, or cybersickness, or the experience of sickness under provocation conditions. Subjective measurements may be impacted by systematic biases and psychological factors (Jahedi and Méndez 2014), and thus there is a trend to devise more objective measures of cybersickness (Bouchard et al. 2011; Bruck and Watters 2011; Cowings et al. 1986; Gavgani et al. 2017; Kim et al. 2005; Nalivaiko et al. 2015). These objective measures are of particular interest in training domains where independent identification of susceptibility, or affectedness, can assist in maximizing training experiences, minimizing postexposure effects, and optimizing content to reduce provocation.

Objective approaches focus on the measurement of physiological responses to cybersickness (Kim et al. 2005). The key physiological changes include sweating, alterations in gastric myoelectric activity and in cardiac vagal tone, an increase in the delta-power of the EEG, and a rise of plasma vasopressin (Stern et al. 2011). In one study, 16 electrophysiological parameters where collected while subjects navigated a virtual environment (Kim et al. 2005). During this provocation, some parameters increased (gastric tachyarrhythmias, eye blink rate, skin conductance, respiratory sinus arrhythmia, and delta-power of the EEG), while other decreased (heart period, fingertip temperature and photoplethysmographic signal, and EEG beta-power). Of those changes, several (gastric tachyarrhythmias, eye blink rate, respiration rate, respiratory sinus arrhythmia, and heart rate) had significant positive correlation with the subjective score of cybersickness. In a further study, immersion in a virtual environment resulted in an increase of the low-frequency but not high-frequency components of the heart rate variability (Ohyama et al. 2007). In conjunction with the previously mentioned work, this may indicate that cybersickness is associated with an increase of the cardiac sympathetic outflow.

It is less known but well documented that motion sickness causes disturbances in thermoregulation (Nalivaiko et al. 2014) that manifest as dilatation in the cutaneous vascular bed and reduction in thermogenesis; it is quite likely that "cold sweating" is a part of this thermoregulatory response. The dilatation of cutaneous vessels during provocative motion has been confirmed in experimental animals (Ngampramuan et al. 2014) and thus appears to be a cross-species real-time marker of motion sickness (Nalivaiko et al. 2014).

It appears that objective signs of cybersickness resemble those of other types of motion sickness; it is however not known whether subtle differences exist, similar to differences in symptoms between motion sickness, cybersickness, and simulator sickness. In the future, it is likely that both objective and subjective approaches will be used to help design better devices and experiences in Virtual Reality that improve understanding of this complex condition while helping to minimize the commercial impact of cybersickness. Further detail around cybersickness can be found in a recent systematic review (Davis et al. 2014).

Synonyms

Action role-playing game; Adventure game

Definitions

Adventure game = A game genre where the players are motivated by exploration, the unknown, and solving puzzles.

Action role-playing game = a game genre combining elements of both action and role-playing games. Players assume the role of a character in their unique world. Combat is done in real time as opposed to turn-based games.

Dark Souls III Action-Adventure Role-Playing Game

Dark Souls III is an adventure and action role-playing game developed by From Software and published by Bandai Namco. *Dark Souls III* came out in Japan on March 24, 2016, and later to the rest of the world on April 12, 2016. It is both a single and multiplayer game that was released on Xbox One, PlayStation 4, and other consoles with an M rating. *Dark Souls III* is the third game in the *Dark Souls* franchise.

In *Dark Souls III*, the player fights their way through countless enemies as they progress through the game. *Dark Souls III* takes pride in being one of the most difficult games that gamers can find. The gore and character designs heavily aims for an adult audience.

This is a game that has very few cutscenes; instead, the game relies on in-game item descriptions and dialogue with the NPC's to tell the story. *Dark Souls III* is set in the fallen country of Lothric. In the beginning of this world, the only beings in existence were the immortal dragons. After the discovery of fire, multiple types of life began to come out of the darkness.

This started the cycle of fire and darkness. At the start of the game, the players are awakened by

Dark Souls III, an Analysis, Fig. 1 Character creation also lets players customize almost every aspect of a character

the sound of a bell that is warning that the fire is in danger of going out. This leads them to a building where the fire is located. What they find is that only one of five of the Lords of Cinder remains to keep the fire lit. Their job is to go and defeat the other lords and bring them back to the fire. The Lords of Cinder are Ludleth of Courland, Abyss Watchers, Aldrich the Devourer of Gods, Yhorm the Giant, and Lothric the Younger Prince.

In *Dark Souls III,* the player starts the game in a character creation screen (Fig. 1). Here they choose an origin that gives them stats that are based on the origin. An example of this would be that a knight will have default stats that are suited for melee combat, like strength.

Dark Souls III has bonfires that are placed around the map. These bonfires are lit by walking up to one and lighting them. These bonfires are save points which will reset health and estus flasks. These bonfires also act as a fast travel system to go from one bonfire to another.

The combat in this game is based on figuring out the patterns and attacks the enemies use to dodge, block, or counter their attacks. The health system in the game uses what are called estus flasks. They give portions of health back. Players can collect in game items to increase the number of flasks they have and how much health they will restore. The magic in this game has the same type of system but they are another type of flask called ashen estus flasks. The catch is that the health flasks and magic flasks are connected, meaning that players can only have seven total flasks at once. The ratio of health to magic flasks can be adjusted in-game at the blacksmith.

The stamina system in *Dark Souls III* is set so that as a player runs, stamina will deplete. If one stops running, their stamina will fill back up. Stamina also depletes each time they use a weapon or dodge (Fig. 2). The amount of stamina a player has can be increased by leveling up their stats.

In *Dark Souls III,* when a player dies, they will start to become hollow. The more they die, the more hollow they will become. Hollowing is an effect that will gradually start to lower the max amount of health they will have. This will also start to make their character look more and more decayed. The way they can reverse the effect is to find embers that are scattered around the map.

Dark Souls III, an Analysis, Fig. 2 The picture above is to show the games interface. In the top left corner is the red health bar, blue magic bar, and green stamina bar. In the bottom left corner, there are equipment boxes. Inside these boxes are usable items and weapons will be displayed. The bottom right corner has a counter showing the number of souls collected

Once a player uses one, their health's max level will go back up and their character will look normal again. This state is called being embered. Hollowing also prevents multiplayer. If a player dies, their loot will be dropped where they died. If they die again before returning to collect the loot, they will vanish.

Dark Souls III has a mechanic in the game that limits the amount of items players can have on their person by weight. The less weight players have, the faster their character can move. This is shown to the player in a percentage. If they are below 30% of max weight capacity, they are faster than normal. The normal weight range is between 30 and 70%. At this weight, they are moving at the normal speed of their character. At 70% or higher, the character will slow down drastically. Movement speed and dodging speed will go down and stamina will regenerate slower. If it is over 100%, they will no longer be able to run or dodge. The game calls this state being overburdened. A player can increase their max carrying capacity by leveling their stats.

In this game, the currency, called souls, is used to buy equipment or upgrades. Souls are dropped by enemies. These are traded in to different NPC's to upgrade stats or to get new equipment. Souls can also be used to upgrade the equipment that they already have.

To upgrade the equipment, players have to find in-game items that match the specific weapon they are trying to upgrade. Along with these items, players will need a certain amount of souls to upgrade as well. A piece of equipment can be upgraded a total of ten times. Each time the equipment will get stronger but the amount of items they need to upgrade the equipment will also increase.

Dark Souls III has a unique style of multiplayer. There are items in the game that can be used to make a mark on the ground. This mark can be seen by other players in their game if they are in the area. The player will have to go and accept the player so he can join the other player's game. They can put down a red or white mark. A red mark will bring them to another's world as an enemy and a white mark will bring them as an ally. There is a feature where a player can invade another's game. This will make them unable to progress unless the defeat the invaders or they are defeated themselves.

The levels in *Dark Souls III* are designed so that players fight through enemies to clear out the

area and collect all of the items in the area. If players die while clearing the area, the enemies that they killed will respawn. Each level has a boss at the end that they have to beat to continue. There are some optional bosses that do not need to be beaten to continue. These bosses are found in optional levels that branch off from the main levels. As players fight through the levels, the enemies' difficulty increases, as does the number of souls they drop. The items that they drop and the items they can pick up from the world will also increase in value.

Dark Souls III had great public reviews. Gamespot.com rated *Dark Souls III* as an 8/10. PC Gamers rated the game a 94 out of 100. Metacritic rated the game 89 out of 100. *Dark Souls III* has no notable controversies.

There have been many improvements to the franchise since the first game. The second game improved the hollowing system by adding the lowering of the health cap. *Dark Souls III* further improved this system by adding dark sigils. The more sigils a character has, the more the hollowing affects them. *Dark Souls III* is also the first game in the series to introduce the magic bar. In the previous games, spells were limited use and could be restored at a bonfire. The games also had graphic upgrades from game to game. The pictures from top left to right (Fig. 3) show the graphical upgrades.

Dark Souls III, an Analysis, Fig. 3 There are two games made by the same developer that are similar to these games. The first is the game that was released before the original *Dark Souls*, and it is called *Demon Souls*. The next game called *Bloodborne* is also very similar to the *Dark Souls* franchise and was developed by the same developers. *Nioh* and *Lords of the Fallen* are games that are also similar to *Dark Souls III*. These two games are made by different developers and have different plots, but they have the same style of clear an area and then fight a boss gameplay

Synonyms

Action RPG; Soulslike

Definition

RPG = A roleplaying game where the player controls the actions of a character in an immersive virtual world.

Dark Souls = An action RPG released in 2011, which has gained infamy in the gaming industry for its high difficulty.

Introduction

Dark Souls is a notoriously difficult video game that alienates most people from trying it. This article explains what makes Dark Souls a good game through the description of its gameplay systems, and how its difficulty makes it a more worthwhile experience.

From Software, the developer of *Dark Souls,* didn't always have the booming success that it has today. It was originally formed in 1986 as a developer for office software, but in 1994 it jumped onto the gaming scene with *King's Field* for the PlayStation*,* a first-person dungeon crawler RPG that saw the player explore dungeons, solve puzzles, and fight monsters. *King's Field* retained the level of difficulty that the *Souls* series would eventually be known for, but a lot of the difficulty came from the bizarre controls and obtuse puzzles. *King's Field* would spawn a few more sequels on PlayStation 1 and 2, but it never had the success that other competing RPGs like the *Final Fantasy* series did (Ciolek 2015).

In 2009, *Demon's Souls* was released to not much fanfare. It was originally only released in Japan, but Western players were able to import it and find a difficult but rewarding experience. This convinced Atlus to publish the game in the West, where it found immediate success. *Demon's Souls* is the first Soulslike game From Software ever released, and many of its gameplay systems would be refined and implemented into *Dark Souls* (Ciolek 2015).

Dark Souls was released in 2011 for the Xbox 360 and PlayStation 3. It received universal acclaim from critics and was cemented as a hallmark of gaming. As of 2022, the *Souls* series has sold 27 million copies (Hannah 2021).

Plot

Making sense of the plot to *Dark Souls* can be a daunting task for newcomers. Aside from the

opening cutscene that plays when the player starts a new playthrough, the game doesn't explain its story very well. Every secret about the game's world and its lore must be found by the player, whether that be through character interactions or by reading item descriptions. This adds a level of immersion unmatched by most other games, as the player is learning with their character, but it's entirely possible to beat the game without understanding the plot.

The player controls the Chosen Undead, an undead warrior prophesized to prolong the Age of Fire by ringing the Bells of Awakening. However, this prophecy is misleading, as many undead have undertaken the pilgrimage and failed. Those that have failed became hollow and lost their sanity. The Chosen Undead is not actually chosen by anyone, rather, it could be said that the Chosen Undead is whoever is able to ring the bells first ("Dark Souls Lore Explained!" 2020).

Gameplay

Dark Souls has combat like most 3D *Zelda* games: the player can attack, dodge, and lock on to enemies, and a lot of time is spent hiding behind a shield. What sets *Dark Souls* apart from *Zelda,* however, is resource management. *Dark Souls* has a stamina bar that drains with nearly every action the player can perform. This includes sprinting, attacking, and dodging. This means that if the player spams the attack button until they run out of stamina, they won't have any stamina left to dodge an incoming attack until the bar refills. Patience, timing, and careful stamina usage are important in order to succeed in *Dark Souls.*

Along the journey, the player will find bonfires. Bonfires act as checkpoints for the player, and allows them to replenish their health, magic, and Estus Flask, a magical healing drink that the player can use a limited number of times before resting at a bonfire. However, bonfires will also respawn all previously defeated enemies except for bosses.

When the player dies, they respawn at the last bonfire they visited and they lose all their souls, which act as both experience points and a currency. The player has one chance to return to the spot where they died in order to retrieve them, but if they die again before that happens, their souls are gone forever.

If the player character was human before they died, they will become hollow. Hollowing will change the player's appearance to that of a zombie and disables the summoning of NPCs or other players for bosses. On the other hand, it also protects the player from invaders, other players with their own copies of *Dark Souls* whose only goal is to kill the player. Depending on the situation, being hollow can be either a detriment or a benefit.

The world of *Dark Souls* is massive, but linear. It wouldn't be inaccurate to compare the structure of the map to that of a Metroidvania, as the player slowly unlocks more of the map as they play, and they have the option to use shortcuts to access different areas quickly. Players can complete certain objectives out of order, but they still must be done in order to beat the game. For example, at the beginning of the game the player is tasked with ringing two bells: first, one in Undead Burg, and then one in Blighttown. Depending on how they start, the player could ring these bells in any order they want, but they must ring both before they can do anything else.

A Reputation for Difficulty of *Dark Souls*

Dark Souls has built up a reputation of being one of the hardest games one could ever beat. Many gamers are intimidated from trying *Dark Souls,* or any other Soulslike games, due to this difficulty. Despite this, the *Souls* series has plenty of devoted fans that sing its praises, and *Dark Souls* is seen as one of the best games ever made.

Dark Souls is not an easy game. It's likely that first-time players will die hundreds of times before they see the ending, so some players may begin to feel frustrated if they are not making progress, which isn't helped by the fact that the player will lose all their souls every time they die. Unless the lost souls were enough for the player to level up, its generally not worth going back for them. It's also recommended to spend all souls before venturing into a new area or fighting a boss.

The game also doesn't always make it clear where players are supposed to go or how certain mechanics work. Progression is linear, especially early on, but it's still possible to miss important items if the player doesn't explore. If the player is confused about where to go next, it might be best to look up the solution online or they might be wandering around for hours.

As the player progresses, they will find enemies with bigger health pools, and they might feel that they are not doing enough damage. There is a blacksmith named Andre at the end of the Undead Parish that will upgrade weapons and armor. While it's possible to beat the game without ever visiting Andre, the player will be weak, and their weapons and armor will eventually break. It is recommended that the player backtracks to this area occasionally to make sure their gear is up to date.

If the player is stuck on a boss, they have the option to summon an NPC or another player, though NPC summon signs are often hidden and there isn't a guarantee other players will be online. If summoning was fruitless, it might be worth grinding or traveling to a different area, if possible.

Reception

Dark Souls is unlike most action RPGs that came before it. It can be ruthlessly difficult sometimes, but the gameplay is tightly designed and balanced in a way where the player won't get stuck if they explore every option they have. The satisfaction of overcoming a difficult area or boss also makes continued play more rewarding than many other action RPGs as well. The experience of playing *Dark Souls* has stuck with many gamers. Keza MacDonald of IGN gave it a 9 out of 10, saying that it was "one of the most thrilling, most fascinating and most completely absorbing experiences in gaming" (MacDonald 2011).

At the 2021 Golden Joystick Awards, *Dark Souls* won the award for Ultimate Game of All Time, beating out many other immensely popular games like *Doom, Minecraft,* and *The Legend of Zelda: Breath of the Wild* (Ammerman 2021).

[2]Vincennes University, Vincennes, IN, USA

Synonyms

Dark souls; Essential experience; Player experience

Definition

Lens of essential experience – A critical thought process by applying the concept of player experience in scrutinizing or analyzing a game

Former Disney game designer Jesse Schell stated that every memorable experience has

some key features that define it and make it special (Schell 2015). Without an impactful experience, how would video games be popular mediums of entertainment? The lens of essential experience encourages game designers to create a whole new world, whether familiar or alien, to witness something that its consumers could not find through any other means. We humans experience things every single day, yet some of us still seek video games to fill our inquisitive minds. One exemplification of games that portray excellent player experience is Dark Souls, a third-person action role-playing game developed by FromSoftware and published by Namco Bandai Games in 2011 for PlayStation 3 and Xbox 360. Dark Souls is known for its impossible level of difficulty, but it still managed to become a classic within the gaming community's collections.

Dark Souls answers the three questions for the lens of essential experience: "What experience do I want the player to have?", "What is essential to that experience?", and "How can the game capture that essence?". As stated before, Dark Souls is known for its unbearable difficulty. How could a game so difficult deliver such a memorable experience? It is simple: the value of experiencing the massive world, bosses, and lore helps make this a game to play. These elements are essential to being able to have an impactful experience. The difficulty itself is the most unique experience a person can have; without it, this game would not have been as popular of a game as it is.

The player must learn and observe the world that Dark Souls sets in front of them. The only reason Dark Souls is considered difficult may be because the player is thrown into an unfamiliar environment. Of course, this is not a game that a player can just jump into and expect positive results; it's up to the player to figure out the mechanics, the boss's attack patterns, and the map they are thrown into. The player takes the role of a handcrafted character that they may create themselves. The player has free reign over the character that they assemble; this means the player gets to experience the world around them in a whole new light. Game director and producer Hidetaka Miyazaki modeled various places in the game after real-world locations including the Milan Cathedral in Italy. As the player progresses through this lustrous world, they encounter many challenging bosses as they venture forward to succeed Lord Gwyn to fulfill the prophecy of returning the Lost Soul to the First Flame.

Defeating bosses is the main objective, but the player must first explore each map as well as learn the lore around the areas they encounter. The player virtually gets to undergo this world without limits as it is an open-world game; this means the player gets to experience the game as they please, not being directly pointed in the right directions. In fact, the player is not spoon-fed with the quests they must undertake. The player as a character must decide on how to commence their adventure. There are many different routes the player may take to complete the game. This is an interesting idea as it means that their characters get to adventure forward as they so choose.

Among just experiencing the world alone, they have the option of inviting friends to ally them on their journey or being invaded by enemy players who are also playing the game. Friends enable an even higher level of difficulty because the bosses increase their stats with each new ally. Enemy players all have the objective of killing the player on their adventure. In Dark Souls the player must approach bosses and the world around them with an open mind, learn the patterns of the bosses, and explore alternative pathways around the world all while cooperatively traversing with friends or being attacked by foes.

All these elements of Dark Souls capture the essence of experience. If any one of these attributes had been excluded from the final build of the game, it would not have done as well as it did. The lens of essential experience is an important lens for creating a masterpiece, and Dark Souls clearly shows how, if applied correctly, someone can develop a phenomenal video game.

Deafblind communication interfaces; Extended Malossi alphabet; Gesture-based interactions; Hand and finger motion tracking; Motion and posture analysis

Definition

Data gloves are wearable devices with incorporated sensors that allow for motion and posture tracking of the user's hands and fingers. Since direct sensing is employed, there are no environmental restrictions and timely, highly reliable data can be collected. Motion interactions are then implemented through real-time analysis and recognition of the user's hand and finger postures and gestures. The employed nonoptical sensing method is particularly suitable for interactions of deafblind users through an extended Malossi alphabet.

Introduction

The first report of a finger motion tracking data glove (DeFanti and Sandin 1977) appeared in 1977 and was followed by various research efforts and implementations of glove-based input for hand and finger motion digitization (Sturman and Zeltzer 1994; Dipietro et al. 2008). The direct tracking of finger motions pursued by this approach is of particular interest in areas where gloves are considered indispensable. Data gloves can be employed, for example, in medical training, where surgical gloves are mandatory for many medical procedures. For adequate experience, such data gloves should match the physical properties of the surgical gloves and provide very similar touch and feel. To achieve this, novel materials are nowadays specifically designed to meet the requirements of the target application domain. In addition, recent technological advancements are employed for implementing finger motion tracking sensors that blend into the glove fabric and allow for seamless integration.

The early wired glove designs (DeFanti and Sandin 1977) employed embedded optical sensors constructed from light emitters and photocells. The components of the optical sensors were connected by flexible rubber tubes that bended following the motions of the human fingers (Zimmerman 1985). In result, the light reaching the photocells decreased proportionally to the tube bend and thus controlled the output voltage of the photocell. A later method (Harvill et al. 1992) employing optical fibers with an intentionally damaged surface that attenuated the light propagation proportionally to the bend lead to

the construction of more flexible and easier to handle optical sensors. More advanced fiber-optic sensors based on double cladding fiber (Ivanov and Chertoriyskiy 2015) were also employed in high-end gloves such as the Virtual Programming Languages (VPL) Dataglove (Zimmerman et al. 1986).

Capacitive and resistive bend sensors (Neely and Restle 1977) on the other hand were used in consumer-grade products such as the Nintendo Power Glove (Gardner 1989). Note that some bendable resistive sensors for wired gloves were produced by applying conductive inks to a flexible substrate (Langford 1996). However, such bendable sensors tend to produce an asymmetric response since conductive inks on a flexible substrate are more sensitive to expansion than to compression.

Sensing of the bending is often insufficient when high fidelity finger motion tracking and the detection of subtle finger movements are targeted. For this, stretchable sensors employing either capacitive (Hirata et al. 2015; Tairych and Anderson 2019; Glauser et al. 2019) or resistive (Firouzeh and Paik 2015; Sbernini et al. 2016; Lee et al. 2018) technologies appear to be more suitable.

Advanced Carbon Nanotube (CNT) Based Sensors

Rapid-response widely stretchable sensors are indispensable for the detection of the subtle human hand and finger motions. Those are specialized sensors derived from the recent research on the synthesis of vertically aligned ultralong multiwalled carbon nanotubes (CNT) using iron chloride powder (Inoue et al. 2008). The unique process essential for the reliable and cost-effective fabrication of the CNT material embedded in such high-fidelity motion tracking sensors is as follows.

A 2.1-mm long CNT array is first grown by conventional thermal chemical vapor deposition on a quartz surface with a single gas flow of acetylene for 20 min. It is then spun into a yarn, thus converting the three-dimensional array into a horizontally aligned web. Afterward, well-aligned CNT sheets are fabricated by stacking and shrinking the CNT Webs (Inoue et al. 2011).

Experimental CNT strain sensors are manufactured by placing the CNT sheet on a flat and smooth substrate (e.g., glass) in a direction parallel to the stretching direction and impregnating it with elastomeric resin. This process requires a rubber-like elastomeric resin with low elasticity and low-loss properties such as polycarbonate-urethane (PCU) and segmented poly-tetramethylene ether glycol-urethane (PTMGU) to enhance the contraction properties of the substrate (Suzuki et al. 2016).

To further stabilize the contraction behavior of the sensor, an elasticity-assist layer is applied on top of the elastomer resin surrounding the CNT bundle. Since the resistance naturally increases with strain due to the cracking of the CNT sheet network, obtained elasticity can be adjusted by changing the number of layers in the employed CNT sheets. This enables the construction of stretchable sensors with predefined resistance that allows for more accurate motion tracking.

Note that the sensor resistance is proportional to the applied tensile strain that increases with the applied force. The temporal strain changes are closely followed by the variation of the strain sensor resistance that can exceed 200%. The excellent rapid response of the sensors has been confirmed through a large number of resistance measurements during sensor extensions and contractions at different frequencies (Suzuki et al. 2016). This has also confirmed the high linearity of the resistance variation with respect to the strain that further increases the motion and posture tracking precision.

Different versions of the specialized stretchable CNT-based sensors have been commercialized and are currently employed in Yamaha data gloves (Suzuki et al. 2016).

Applications and Implementation Examples

Data gloves employing CNT sensors discussed in the previous section are capable of high fidelity motion tracking (Gelsomini et al. 2021). The

Data Gloves for Hand and Finger Motion Interactions, Fig. 1 A data glove with embedded highly stretchable CNT sensors connected to a dedicated wireless communication device

Yamaha data gloves, for example, are employed for tracking of the subtle hand and finger motions during the play of different musical instruments. Note that such motion tracking has to be implemented with a minimal burden to the artist so that the free natural movements of the hands and the fingers of the player are unimpeded. To facilitate this, a wireless data glove version has been developed as shown in Fig. 1.

Data gloves have been employed in a number of research projects, beginning with an experimental control of a robot hand in exergaming and implementation of hand-based interactions with mobile robots (Demoe et al. 2020). This has been extended with a more general model for data glove-based human-robot communications including experimental support for deafblind through an extended version of the Malossi alphabet (Gelsomini et al. 2022). There is work in progress on the integration of optical and data gloves input for improved sign language analysis and interpretation through machine learning (Raavi et al. 2022).

With respect to medical applications and training, data gloves have been instrumental in researching the user experience aspects in wearable multi-device applications designed for health systems (Salgado et al. 2021) and in conducting experiments related to psychomotor-based virtual medical training (Wilcocks et al. 2021).

Conclusions

The early data gloves incorporated optical sensors consisting of light emitters and photocells connected with flexible rubber tubes. This allowed for tracking of the finger motions with a limited precision through measurements of the attenuated light reaching the photocells. In more advanced applications where higher fidelity finger motion tracking is required, stretchable sensors are deemed more appropriate, and active research is continuing in this field.

Dead Space Through the Lens of Resonance

Devon Myers[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Survival horror

Definitions

Survival Horror – a subgenre of action-adventure and horror genres where players are frail and are given few weapons, forcing them to approach obstacles through problem-solving rather than combat.

Introduction

The Lens of Resonance is to be mainly associated with how powerful a game makes a player feel and if it gives a good consistency of this power throughout the game. If the player were to feel like they are barely making a difference within the game it may cause the player to feel as if the journey is pointless and may discontinue the game due to this. This can be achieved through many ways, such as completing a certain campaign mission, giving a character powerful attributes, or even giving the character a powerful music ensemble that gives the player a sense of what events are important. Giving players a sense of power can go all the way back to Pong, one of the very first, if not the very first game. It gave the player a feeling of power after winning a game, bragging rights.

In Jesse Schell's book *The Art of Game Design: A Book of Lenses*, the Lens of Resonance states that "to use the Lens of Resonance, you must look for hidden power" (Schell 2019). The Lens of Resonance asks the following questions:

1. What is it about my game that feels powerful and special?
2. When I describe my game to people, what ideas get them really excited?
3. If I had no constraints of any kind, what would this game be like?
4. I have certain instincts about how this game should be. What is driving those instincts?

Dead Space is a survival horror franchise that was published and released by Electronic Arts (EA). There are three games in the franchise. *Dead Space* was released in 2008 for the Xbox 360, Playstation 3, and Windows PC. *Dead Space 2* was released in 2011 for the Xbox 360, Playstation 3, and Windows PC. *Dead Space 3* was released, once again, for the Xbox 360, Playstation 3, and Windows PC in 2013. Rather than making a player feel powerful, the games instead tried to make them feel as weak as possible with methods such as starting the game with a very small health. Story wise, the player character is one of the only humans left on a spaceship full of aliens trying to kill them in several gruesome ways. Progressing through the story gives players new weapons and abilities while also maintaining the very fragile health bar, which gives them a very good sense of power while also severely limiting abilities with their health.

Dead Space made itself different from other games in the horror genre at the time by having the game's setting be in space. The vast emptiness of space can be very unnerving even when the game is at a lull. It can also make the player wonder what other aliens are out there and where they came from. Other than the horror aspect, players loved the look, lore, and the difficulty in killing the aliens.

As in several other horror games, *Dead Space* has several constraints to make the game more interesting, such as having limited ammo and a very weak melee attack that makes players second guess their actions in a game where reactions are everything. Players that plan poorly or act rashly can find themselves in a situation where they run out of ammo and have to resort to their weak melee attack or find a way to bypass an alien

obstacle entirely. If the creators did happen to have no constraints, then there could be aspects such as having unlimited ammo, an increased health bar, and possibly even gorier animations. If these were implemented into the game, it would make the game too easy to beat and defeat the horror purpose. Other horror genre aspects include overly graphic and displeasing animations from the aliens which would not be suitable for the weak-willed.

EA knew that they wanted to bring a new breath of fresh air to the horror genre while keeping a constant pace of action within the game as well. But as the franchise developed, EA's drive changed from survival horror to add more action genre aspects to *Dead Space*. Due to this influence from the action genre, the horror aspects were overshadowed at some points during *Dead Space 3*. This was a common complaint from several critics and the playerbase. Statistics show that people much prefer the first and second games over the third, and this is again because of decreased focus on horror while maximizing the importance of the action sequences.

Decoupling Game Tool GUIs from Core Editing Operations

Decoupling systems; Plugin system; Command system; Editor architecture; Game level editor

Definition

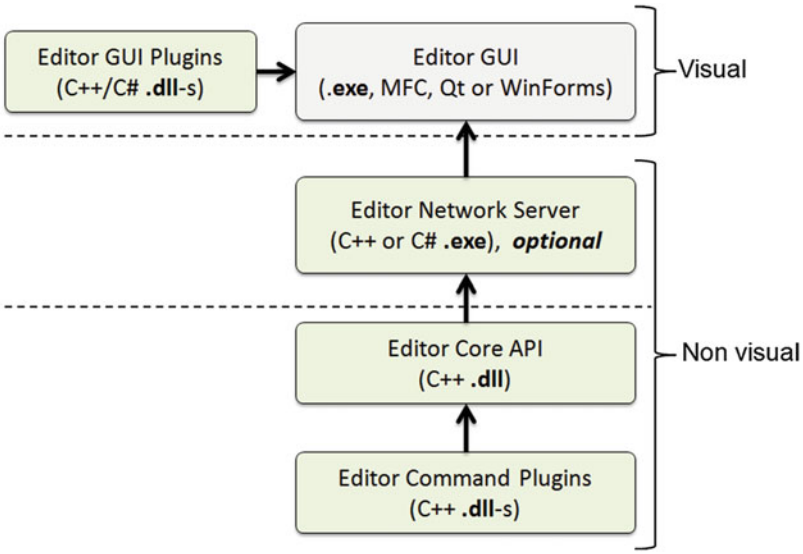
A software architectural method of decoupling the game editing operations from the actual GUI of a game level editor.

Since the early days of video game development when the programmer had to write the code and design and create the levels without the aid of a game editor, the tools to create games have evolved into the must-have game development software we use today. Now the level editors are built into the development kits, and the developer's job is much easier but still filled with potential pitfalls.

In the past few years, it has become common to decouple game level editor operations and functionality from game-specific features, so that the editor can be reused for more games and game types. The same thing has happened on the game engine side: engines have become more and more flexible and reusable.

But problems remain. One big issue with game level editors is complexity and manageability. Once you have added many features to the editor, it will grow in source code size and complexity and become harder and harder to maintain and extend. Another problem is that you have to choose a GUI toolkit to create your interface. That can become a headache if you ever decide to switch to another GUI toolkit, since many editing operations are tied in with the UI code itself.

To address the issue of changing GUI toolkits in these fast and ever-shifting times, we present a



Decoupling Game Tool GUIs from Core Editing Operations, Fig. 1 The editor ecosystem

method of decoupling the visual user interface code from the non-GUI editing operations code in the game level editor or other tools. By separating the UI from core editing functions, you can change to another GUI toolkit in no time, leaving the editing operation code almost untouched. The decoupling operation can be accomplished via C++ editor core functionality code and various editor user interfaces using GUI toolkits like Qt, MS WinForms, WPF, MFC, HTML5/JavaScript, or even a command line editor UI, all using the same editor functionality code as a common hub. Communication between the editor functions and the visual interface is achieved through a command system (basically the command pattern). We will also explore the architecture of a plug-in system using this command communication approach.

Editor Ecosystem

The editor is split into two major logical parts:

- Nonvisual, consisting of the editor core, plug-ins, and their commands (no GUI)
- Visual, created using the UI toolkit of your choice, which will call the commands provided by the plug-ins and editor core

In Fig. 1, we can see the entire editor ecosystem:

The editor GUI can be developed using any UI SDK/API, and it can have its own plug-ins. For example, subeditors like the model editor, cinematic editor, scene editor, material editor, etc. can be hosted by the main editor, and we can even run them as separate tools. Each tool will implement its own UI functionality and will call commands by their name and parameter values (arguments). The editor core will search its registered command list and dispatch the call to the appropriate plug-in command.

We can also have an editor network layer, which waits for tools to connect to it and simply dispatches command calls and sends back their results. There are various other methods of communication between the GUI and the editor core; these methods use IPC (inter-process communication) such as pipes, DDE, and shared memory or files, but sockets are supported on all platforms, so they are the obvious first choice.

Editor Core C++ API

Now let's get to the nuts and bolts of the actual code. First we will declare our editor C++ interface to be used by the plug-ins. We are going to expose plug-in and command methods and

interfaces, a simple history (undo/redo) system, and an event system (used for triggering events in the editor, plug-ins can register themselves as event sinks to receive or trigger events).

Let's start with the building block interfaces related to commands, undo, events, and other primitive constructs. We use a self-contained, independent header file, with only pure interfaces, not relying on external headers so it can be easily wrapped or converted to other languages. (It's especially important to keep the interfaces simple. If you were using something like SWIG (Simplified Wrapper and Interface Generator), e.g., having too many dependencies in the C++ code would complicate things for the SWIG converter, sometimes failing to properly create a wrapper for other languages.)

After we define our simple types like uint32, we define a Handle union to be used as a pointer transporter between the calling application and the editor core internals. This will keep things simpler, since the user can't use the pointer itself anyway (see Listing 1).

Listing 1. A Generic Handle Container.

```
// A generic handle, used to pass pointers in command parameters without
having to know the pointer type

union Handle
{
  Handle()
    : hVoidPtr(NULL)
  {}
  explicit Handle(int32 aVal)
    : hInt(aVal)
  {}
  explicit Handle(int64 aVal)
    : hInt64(aVal)
  {}
  explicit Handle(void* pVal)
    : hVoidPtr(pVal)
  {}
  int32 hInt;
  int64 hInt64;
  void* hVoidPtr;
};
```

We will also need a Version structure to be used in the various version comparisons/validations we will have for the editor API and plug-in versions (see Listing 2).

Listing 2. A Generic Version Holder Structure.

```
// A version structure, holding version information for plug-in
// or editor
```

```
struct Version
{
 Version();
 Version(uint32 aMajor, uint32 aMinor, uint32 aBuild);
 bool operator <= (const Version& rOther) const;
 bool operator >= (const Version& rOther) const;
 Version& operator = (const char* pVerStr);
 uint32 major, minor, build;
};
```

After this, a central point of the editor core API is the main editor interface (see Listing 3), which will provide command, plug-in, and event methods to be used by plug-ins and their commands and also by the main editor skeleton application, which will manage those plug-ins.

Listing 3. The Main Editor Core Interface.

```
// The editor main interface
struct IEditor
{
 enum ELogMsgType
 {
  eLogMsg_Info,
  eLogMsg_Debug,
  eLogMsg_Warning,
  eLogMsg_Error,
  eLogMsg_Fatal
 };
 virtual ~IEditor(){}
 virtual Version GetVersion() const = 0;
 virtual void PushUndoAction(IUndoAction* pAction) = 0;
 virtual bool CanUndo(uint32 aSteps = 1) = 0;
 virtual void Undo(uint32 aSteps = 1) = 0;
 virtual void Redo(uint32 aSteps = 1) = 0;
 virtual void ClearHistory(int32 aSteps = -1) = 0;
 virtual bool RegisterCommand(IPlugin* pPlugin,
         TPfnCommand pCmdFunc,
         const char* pCmdName) = 0;
 virtual bool UnregisterCommand(TPfnCommand pCmdFunc) = 0;
 virtual bool IsCommandRegistered(
         const char* pCmdName) = 0;
 virtual bool RegisterEvent(IEvent* pEvent) = 0;
 virtual bool UnregisterEvent(IEvent* pEvent) = 0;
 virtual bool IsEventRegistered(
         const char* pEventName) = 0;
 virtual bool TriggerEvent(IEvent* pEvent,
```

```
        IEventSink::ETriggerContext aContext,
        void* pUserData) = 0;
 virtual void CallEventSinks(IEvent* pEvent,
        void* pUserData) = 0;
 virtual bool RegisterEventSink(
        IEventSink* pEventSink) = 0;
 virtual bool UnregisterEventSink(IEventSink* pEventSink) = 0;
 virtual IParameterValues* CreateParameterValues() = 0;
 virtual IParameterDefinitions*
       CreateParameterDefinitions() = 0;
 virtual bool Call(
        const char* pCommandName,
        IParameterValues* pParams) = 0;
 virtual void WriteLog(
        ELogMsgType aType,
        const char* pModule,
        const char* pFormat, ...) = 0;
};
```

This is the main editor interface at a glance. Its methods are quite self-explanatory, the most used methods being the Call(...) method, which is used to execute commands by their name and requires a parameter "bag" (optional), and the IParameterValues interface, created before the call by the user using the CreateParameterValues () method and then filling up the parameter values for the command to use.

Plug-ins

The plug-ins are DLLs loaded by the core editor DLL. Each plug-in will expose and register its commands in the editor's ecosystem and provide information about these commands through a manifest file associated with the plug-in's DLL.

A core editor plug-in consists of two files:

- A C++ DLL file, the plug-in code (Example.dll)
- A manifest file (Example.plugin.xml), having the same base file name as the plug-in's DLL (Example), containing information about it

Listing 4 shows an example of a plug-in manifest file.

Listing 4. Plug-in Manifest File.

```
<plugin
  name="Example"
  description="The example editor plugin"
  author="Nicusor Nastase Nedelcu"
  url="http://some.com"
  guid="31D91906-1125-4784-81FF-119C15267FC3"
  version="1.0.0"
  minEditorVersion="1.0.0"
  maxEditorVersion="2.0.0"
```

```
  icon="example.png"
  unloadable="true">
  <dependencies>
    <depends nameHint="OtherPlugin"
      guid="DAA91906-1125-4784-81FF-319C15267FC3" />
    <depends nameHint="SomeOtherPlugin"
      guid="F51A2113-1361-1431-A3EA-B4EA2134A111" />
  </dependencies>
  <commands>
    <command name="get_some_thing"
          info="This command get something">
      <param name="someParam1" type="int32"
           info="this is parameter 1" />
      <param name="someParam2" type="float"
          info="this is parameter 2" />
    </command>
  </commands>
</plug-in>
```

Of course, you can choose any format for the manifest file, like JSON or a custom text format. The important thing is that the plug-in's DLL does not contain any information about the plug-in or its commands. Only the manifest file holds that information.

Plug-ins can be located in a directory structure as shown in Listing 5.

Listing 5. Example of Plug-in and Editor Directory Structure.

```
\Plugins
  \Example1
    Example1.dll
    Example1.plugin.xml
  \Example2
    Example2.dll
    Example2.plugin.xml
EditorCore.dll (the editor code library)
EditorUI.exe (the main editor application)
```

One reason we have chosen to store the plug-in information inside external files is that plug-ins can be listed (with all their details) in the editor's plug-in manager without being loaded into memory. In this way, we can avoid loading some plug-ins we do not need to load but still have information about them. For example, there can be special editor configurations for lighting artists, programmers, or level designers, and these configuration files can be shared among users.

As you can see from the plug-in manifest, we have added information about the name, description, author, and other useful properties but also about the plug-in's dependencies (other plug-in

GUIDs). Optionally, there should be information about the commands, like name, description, parameters, and return values, since we do not store this information in the C++ source files. This information can be used by a debug layer to check the command syntax at runtime and help the discovery of incorrect command calls during development.

For plug-in identification, we will use a GUID in the form shown in Listing 6.

Listing 6. The GUID Structure Used to Identify Plug-ins.

```
// A plug-in unique ID, in a GUID form (see more about Microsoft
// GUID) and online/offline GUID generators
struct PluginGuid
{
  PluginGuid();
  // construct the guid from several elements/parts
  // example:
  // as text: 31D9B906-6125-4784-81FF-119C15267FCA
  // as C++: 0x31d9b906, 0x6125, 0x4784, 0x81,
  // 0xff, 0x11, 0x9c, 0x15, 0x26, 0x7f, 0xca
  PluginGuid(uint32 a, uint16 b, uint16 c, uint8 d,
uint8 e, uint8 f. uint8 g, uint8 h, uint8 i,
    uint8 j, uint8 k);
  bool operator == (const PluginGuid& rOther) const;
  // convert a GUID string to binary
  // string format: "11191906-6125-4784-81FF-119C15267FC3"
  bool fromString(const char* pGUID);
  uint32 data1;
  uint16 data2;
  uint16 data3;
  uint8 data4[8];
};
```

We will use the interface shown in Listing 7 to get information about the discovered plug-ins (gathered from the plug-in manifest files).

Listing 7. The Interface That Describes a Plug-in (from the Plug-in Manifest).

```
struct IPluginInfo
{
  virtual ~IPluginInfo(){}
  virtual const char* GetName() const = 0;
  virtual const char* GetDescription() const = 0;
  virtual const char* GetAuthor() const = 0;
  virtual const char* GetWebsiteUrl() const = 0;
```

```
  virtual PluginGuid GetGuid() const = 0;
  virtual Version GetVersion() const = 0;
  virtual Version GetMinEditorVersion() const = 0;
  virtual Version GetMaxEditorVersion() const = 0;
  virtual const char* GetIconFilename() const = 0;
  virtual bool IsUnloadable() const = 0;
  virtual PluginGuidArray GetPluginDependencies()
              const = 0;
};
```

The plug-in interface methods are easy to understand, but we can say more about the GetMinEditorVersion() and GetMaxEditorVersion(). These methods are used to check whether the plug-in can be loaded into the current editor and help avoid loading plug-ins that are not supposed to run under newer or older editor versions.

The simple creation process of new plug-ins and commands should be the crux of this system; thus, coding new command sets hosted in the plug-ins should be straightforward. In the editor core API, there is an interface each plug-in must implement on its side, called IPlugin, as shown in Listing 8.

Listing 8. The Interface to Be Implemented by a Plug-in.

```
struct IPlugin
{
  virtual ~IPlugin(){}
  virtual void Initialize(IEditor* pEditor) = 0;
  virtual void Shutdown() = 0;
  virtual bool IsCommandEnabled(TPfnCommand pCmdFunc)= 0;
};
```

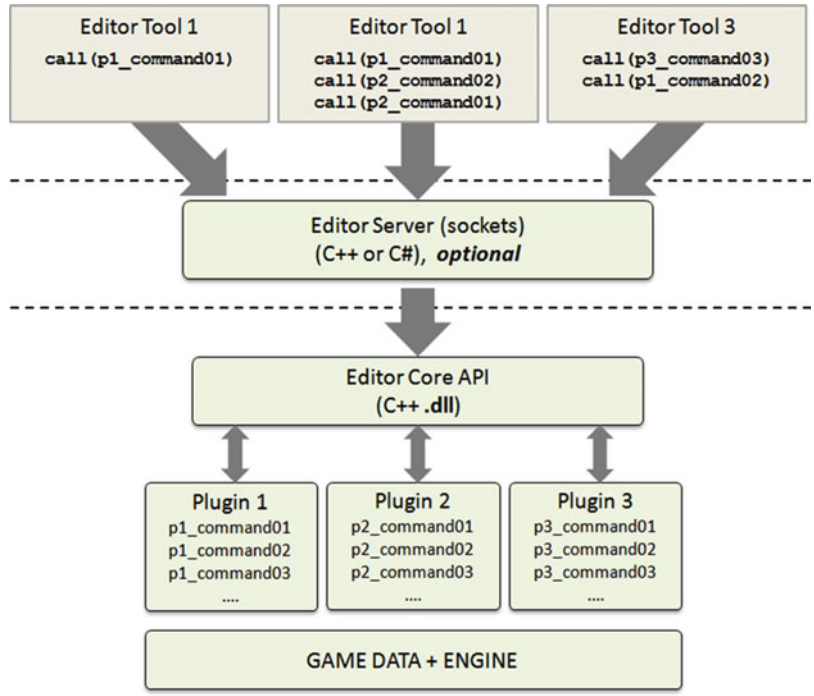
Commands

We will create the editor core as a C++ DLL. This handles the loading of plug-ins that are exposing editing commands. The GUI will call the commands using only the core editor interfaces (see Fig. 2).

The command system is designed as an RPC-like (remote procedure call) architecture, where commands are actually functions that are called with arguments and return one or more values. The call itself can be made directly using the editor core C++ API or the UI editor application connecting sockets to an editor core server, transmitting the command call data and then receiving the returned values.

A command executes only non-GUI-related code so it will not deal with the GUI functions itself, only engine calls and game data. The GUI code will take care of visual representation for the user, and it will call the available commands.

The plug-ins will expose their set of commands, but they will have nothing to do with the GUI itself. You can create a separate plug-in system for the editor's GUI. This is where the true decoupling kicks in, the editor core plug-ins being just "buckets" of non-GUI-related commands with the editor GUI using those commands. There is no need for a 1:1 match between the UI functions and the commands. You only need to expose the basic/simple commands, which should



Decoupling Game Tool GUIs from Core Editing Operations, Fig. 2 The command system diagram

be generic enough to be used by multiple UI tools in various situations.

Command Parameters

When calling the commands, we have the option to send parameters to them, and for this we need to define the parameter type, direction, and description. This information is read from the plug-in's manifest file, but it's optional since the calling of commands is accomplished through a parameter set that is aware of the data types at the moment of setting the values. In Listing 9 we declare the IParameter interface.

Listing 9. The Command Parameter Interface.

```
struct IParameter
{
  enum EDataType
  {
    eDataType_Unknown,
    eDataType_Int8,
    eDataType_Int16,
    eDataType_Int32,
    eDataType_Int64,
    eDataType_Float,
    eDataType_Double,
    eDataType_Text,
```

```
    eDataType_Handle
  };
  enum EDirection
  {
    eDirection_Input,
    eDirection_Output,
    eDirection_InputOutput
  };
  virtual ~IParameter(){}
  virtual const char* GetName() const = 0;
  virtual const char* GetDescription() const = 0;
  virtual EDataType GetDataType() const = 0;
  virtual EDirection GetDirection() const = 0;
  virtual bool IsArray() const = 0;
};
```

The IParameter interface is implemented by the editor core DLL, so plug-in developers do not need to care about the implementation, only what methods it provides, such as the name of the parameter, description, type, direction (if it's an in/out parameter), and whether the parameter is an array of the type specified.

To keep the parameter information in one place, we declare an IParameterDefinitions interface, which holds the parameter information list for a command as seen in Listing 10.

Listing 10. The Parameter Definition Container Interface.

```
struct IParameterDefinitions
{
  virtual size_t GetCount() const = 0;
  virtual IParameter* Get(size_t aIndex) const = 0;
  virtual bool Add(
      const char* pName,
      IParameter::EDataType aDataType,
      const char* pDescription,
      IParameter::EDirection aDirection,
      bool bArray) = 0;
};
```

When calling the commands, we need to pass the parameters. For this, we will use an IParameterValues value "bag," which can set/get parameters and store the values. You can use other approaches for passing parameters, like #define extravaganza or templates to declare several command call forms with from one to ten parameters in their declaration. Listing 11 shows the parameter value interface.

Listing 11. The Parameter Value Container Interface.

```
// Parameter values container, used to pass and receive
// in/out parameter values from a command call
struct IParameterValues
{
  virtual ~IParameterValues(){}
  virtual void SetInt8(const char* pParamName,
                       int8 aValue) = 0;
  virtual void SetInt16(const char* pParamName,
                        int16 aValue) = 0;
  virtual void SetInt32(const char* pParamName,
                        int32 aValue) = 0;
  virtual void SetInt64(const char* pParamName,
                        int64 aValue) = 0;
  virtual void SetFloat(const char* pParamName,
                        float aValue) = 0;
  virtual void SetDouble(const char* pParamName,
                         double aValue) = 0;
  virtual void SetText(const char* pParamName,
                       const char* pValue) = 0;
  virtual void SetHandle(const char* pParamName,
                         Handle aValue) = 0;
  virtual void SetInt8Array(const char* pParamName,
                            Int8Array aArray) = 0;
  virtual void SetInt16Array(const char* pParamName,
                             Int16Array aArray) = 0;
  virtual void SetInt32Array(const char* pParamName,
                             Int32Array aArray) = 0;
  virtual void SetInt64Array(const char* pParamName,
                             Int64Array aArray) = 0;
  virtual void SetFloatArray(const char* pParamName,
                             FloatArray aArray) = 0;
  virtual void SetDoubleArray(const char* pParamName,
                              DoubleArray aArray) = 0;
  virtual void SetTextArray(const char* pParamName,
                            TextArray aArray) = 0;
  virtual void SetHandleArray(const char* pParamName,
                              HandleArray aArray) = 0;
  virtual int8 GetInt8(
                       const char* pParamName) const = 0;
  virtual int16 GetInt16(
                       const char* pParamName) const = 0;
  virtual int32 GetInt32(
                       const char* pParamName) const = 0;
```

```
  virtual int64 GetInt64(
                        const char* pParamName) const = 0;
  virtual float GetFloat(
                        const char* pParamName) const = 0;
  virtual double GetDouble(
                        const char* pParamName) const = 0;
  virtual const char* GetText(
                        const char* pParamName) const = 0;
  virtual Handle GetHandle(
                        const char* pParamName) const = 0;
  virtual Int8Array GetInt8Array(
                        const char* pParamName) const = 0;
  virtual Int16Array GetInt16Array(
                        const char* pParamName) const = 0;
  virtual Int32Array GetInt32Array(
                        const char* pParamName) const = 0;
  virtual Int64Array GetInt64Array(
                        const char* pParamName) const = 0;
  virtual FloatArray GetFloatArray(
                        const char* pParamName) const = 0;
  virtual DoubleArray GetDoubleArray(
                        const char* pParamName) const = 0;
  virtual TextArray GetTextArray(
                        const char* pParamName) const = 0;
  virtual HandleArray GetHandleArray(
                        const char* pParamName) const = 0;
  // delete all parameter values
  virtual void Clear() = 0;
  // get the number of parameters this list holds
  virtual size_t GetCount() const = 0;
  // get the data type of parameter at given index
  virtual IParameter::EDataType GetDataType(
          size_t aIndex) const = 0;
  // get the direction of parameter at given index
  virtual IParameter::EDirection GetDirection(
          size_t aIndex) const = 0;
  // get the data type of parameter at given index
  virtual const char* GetName(size_t aIndex) const = 0;
  // is this parameter an array at given index?
  virtual bool IsArray(size_t aIndex) const = 0;
};
```

To avoid memory fragmentation due to frequent command calls, you would ideally manage the parameter values through a memory pool.

The actual command is a callback function receiving a parameter values set and is declared as shown in Listing 12.

Listing 12. The Command Callback Function Type.

```
typedef void (*TPfnCommand)(IParameterValues* pParams);
```

For debugging and auto-documentation purposes, the editor core API can provide detailed command information through the ICommand interface, which can hold the command description from the plug-in manifest file, plus the command callback function pointer, as shown in Listing 13.

Listing 13. The Command Information Provider Interface.

```
struct ICommand
{
  virtual ~ICommand(){}
  virtual const char* GetName() const = 0;
  virtual const char* GetDescription() const = 0;
  virtual const char* GetIconFilename() const = 0;
  virtual TPfnCommand GetCommandFunc() = 0;
  virtual const IParameterDefinitions*
          GetParameterDefinitions() const = 0;
};
```

Direct Editor API Command Calls

You can call the editor core interface for executing commands directly from C++ or use a wrapper tool for another language like C# (SWIG). To call the commands in C++, we can use the code shown in Listing 14.

Listing 14. How to Call a Command.

```
// create a parameter values bag
IParameterValues* pParams =
          pEditor->CreateParameterValues();
// set some parameter values
pParams->SetInt32("someParam1", 123);
pParams->SetText("someName", "Elena Lenutza Nedelcu");
pParams->SetText("someOtherName", "Dorinel Nedelcu");
// the actual command call
pEditor->Call("someCommandName", pParams);
// retrieve the return values
float fRetVal = pParams->GetFloat("returnSomeValue");
int someNum = pParams->GetInt32("otherValue");
```

Remote Editor API Command Calls

We can use sockets for calling the commands remotely, since they're cross-platform and relatively easy to use from any language or environment. On the editor core DLL side, we will have a network server executable, and on the editor UI side, we will have a network client sending and receiving command data.

Communication can be accomplished through reliable UDP or TCP. For a local editor on the same machine, TCP would be okay even for LAN scenarios. If you are not so keen on using TCP because you consider it slow, UDP should suffice to send commands. All logic remains the same in this networked scenario, but this setup opens the doors to online collaboration of multiple clients operating on the same data on the server. We're not going to discuss this here, since it's a subject for a whole article (a challenging and interesting one!).

Networked editing is also feasible for debugging and remote in-editor live tutorials.

Putting It All Together

Implementing the Main Editor Application

The editor can be implemented in Qt (just an example, chosen for its cross-platform support, though C# can also be supported using Mono on platforms other than Windows). This editor will be an empty skeleton that contains a plug-in manager dialog and nothing else, since all the functionality will be brought in by the plug-ins. Once again we need to emphasize the separation of the plug-in systems. They are two systems, one for the UI and one for the editor core commands. UI plug-ins will use the commands found in the editor core plug-ins (see Fig. 1 at the beginning of this article). The main UI editor can even do without a plug-in system if it's so intended, but the editor core command plug-ins will still exist.

Implementing a Plug-in with Commands

To ensure that you have a simple way of implementing new commands, the method of declaring commands and plug-ins must be straightforward.

In the editor core API, the IPlugin is the interface a plug-in must implement. To help rapid plug-in development, you can write a series of macros. In our sample plug-in, implementing a few commands would look like the code shown in Listing 15.

Listing 15. A Sample Plug-in Implementation.

```
#include "EditorApi.h"
void example_my_command1(IParameterValues* pParams)
{
  // get our calling parameter values
   int numberOfHorses =
       pParams->GetInt32("numberOfHorses");
  std::string dailyMessage =
       pParams->GetText("dailyMessage");
  // do something important here for the command...
  // return some parameter values
  pParams->SetDouble("weightOfAllHorses", 1234.0f);
  pParams->SetText("userFullName", "Iana Lomos");
}
void example_my_command2(IParameterValues* pParams)
```

```
{
  // now here we'll try to grab an array
  FloatArray magicFloats =
        pParams->GetFloatArray("magicFloats");
  for (size_t i = 0; i < magicFloats.count; ++i)
  {
    float oneMagicFloat = magicFloats.elements[i];
    // do something majestic with the float...
  }
  // we do not need to return any value now
}
BEGIN_PLUGIN
void Initialize(IEditor* pEditor)
{
  REGISTER_COMMAND(example_my_command1);
  REGISTER_COMMAND(example_my_command2);
}
// used to check if a command is disabled at that time
// can be helpful for UI to disable buttons in toolbars
// or other related visual feedback
bool IsCommandEnabled(TPfnCommand pCmdFunc)
{
  return true;
}
void Shutdown()
{
}
END_PLUGIN
```

Note that BEGIN_PLUGIN and END_PLUGIN are macros hiding the start/end of the IPlugin interface implementation. The Initialize method is called when the plug-in is loaded into the editor. We are also registering the plug-in's commands by just referring invoking the global functions example_my_command1 and example_my_command1. The Shutdown method is called when the plug-in is unloaded (no need to call the unregister commands; this can be tracked and executed by the editor core itself, since it knows the IPlugin pointer when the commands are registered). The IsCommandEnabled method is used to verify whether a command has the status of "enabled" so it can be called/executed.

Be sure to name the commands in a way that avoids conflicts. Usually some sort of group naming, like the name of the plug-in and the actual command action name, should be enough, like assets_reload, assets_set_tag, assets_delete, or if you prefer camel-case style, Assets_SetTag.

The generated plug-in will be named example.dll and will be accompanied by its manifest file, example.plugin.xml. Of course the plug-in must export a CreatePluginInstance global function so the editor core can load it and instantiate the IPlugin implementation.

Events

To make the plug-ins aware of events occurring in the editor ecosystem, they can register themselves as event sinks, as shown in Listing 16.

Listing 16. An Event Sink, Which Can Be Implemented by the Plug-ins.

```
// Every plug-in can register its event sink so it can
// receive notifications about events happening in the
// editor ecosystem, coming from other plug-ins or the
// editor core itself
struct IEventSink
{
  // When the event sink call is received, before, during or
  // after the event was consumed
  // The eTriggerContext_During can be used to have
  // lengthy events being processed and many triggered to
  // update some progress bars
  enum ETriggerContext
  {
    eTriggerContext_Before,
    eTriggerContext_During,
    eTriggerContext_After
  };
  virtual ~IEventSink(){}
  virtual void OnEvent(IEvent* pEvent,
            ETriggerContext aContext,
            void* pUserData) = 0;
};
```

The IEventSink::OnEvent method is called whenever an event is triggered by other plug-ins or their commands and broadcast to the registered event sinks. The method receives a pointer to the triggered event interface (see Listing 17).

Listing 17. An Event, Implemented by the Trigger Code.

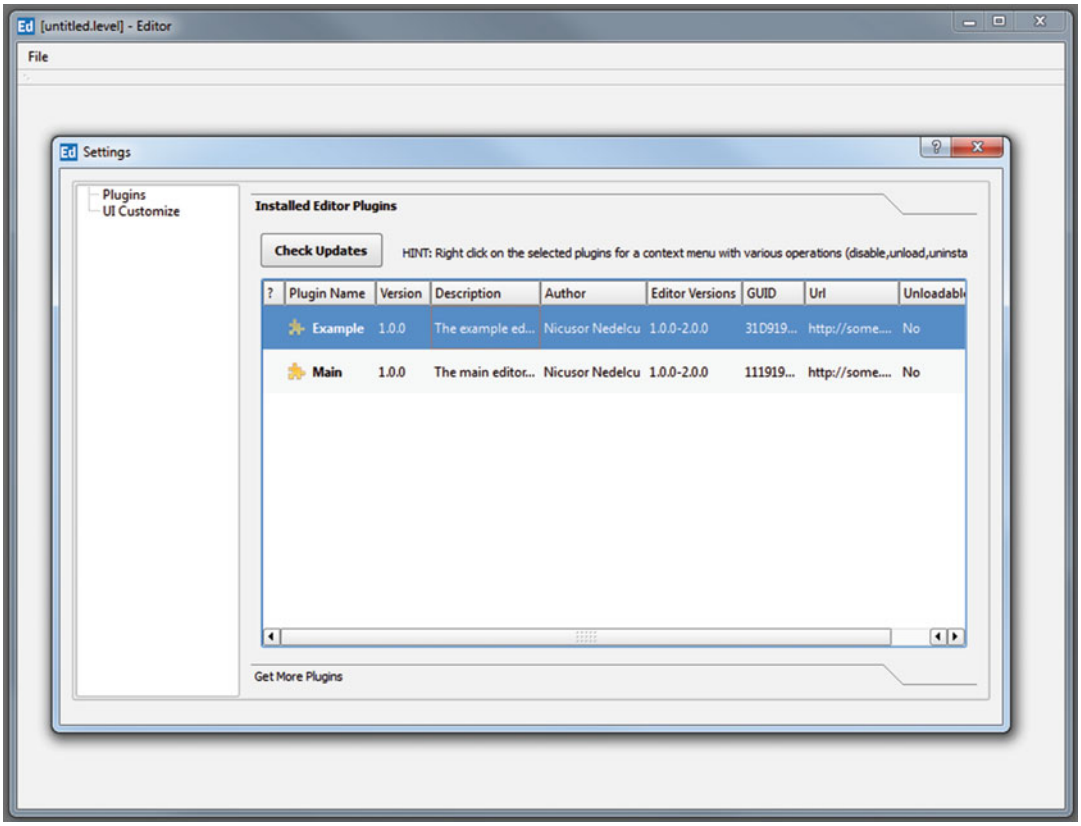
```
// An event is triggered when certain actions are happening
// in the editor or its plug-ins. For example we can have an
// event at Save level or an object moved with the mouse
struct IEvent
{
  virtual ~IEvent(){}
  virtual const char* GetName() = 0;
  virtual void OnTrigger(void* pUserData) = 0;
  virtual void* GetUserData() = 0;
};
```

Listing 18 shows how to trigger an event.

Listing 18. Creating, Registering, and Triggering an Event.

```
// we declare an event
struct MyEvent: IEvent
{
  virtual const char* GetName()
  {
    return "MyCoolEvent";
  }
  // this will be called when the event is triggered,
  // before being broadcast to all the event sinks
  // so the event can even modify the user data
  virtual void OnTrigger(void* pUserData)
  {
    // modify or store the pUserData
    m_pData = pUserData;
  }
  virtual void* GetUserData()
  {
    return m_pData;
  }
  uint8 m_pData;
} s_myEvent;
// we register an event (usually in the Initialize method
// of the plug-in)
...
REGISTER_EVENT(&s_myEvent);
...
// in some command, we trigger the event
void my_command(IParameterValues* pParams)
{
  uint8* pSomeData;
  // ....... do things with pSomeData
  g_pEditor->TriggerEvent(
        &s_myEvent,
        IEventSink::eTriggerContext_After,
        pSomeData);
}
```

In some plug-ins, an event sink registered for a particular event would be notified of the event being triggered, as shown in Listing 19.



Decoupling Game Tool GUIs from Core Editing Operations, Fig. 3 Skeleton editor UI application and settings dialog, with the plug-in manager (made with Qt)

Listing 19. Creating and Registering an Event Sink.

```
// declare our event sink
struct MyEventSink: IEventSink
{
  void OnEvent(IEvent* pEvent,
        ETriggerContext aContext,
        void* pUserData)
  {
    // is this the event we're looking for?
    if (!strcmp(pEvent->GetName(), "MyCoolEvent"))
    {
      uint8* pEventData = pEvent->GetUserData();
      // ...do things when that event was triggered
    }
  }
} s_myEventSink;
// inside the plug-in's Initialize method, register
```

```
// the event sink
...
pEditor->RegisterEventSink(&s_myEventSink);
...
```

In Fig. 3, you can see a demo application of this system, with the editor skeleton having just one menu item, and a setting dialogue where plug-ins are managed.

Conclusion

Decoupling the UI from core editing functionality helps the development and fast feature-set iteration of game creation tools, since fewer hard-coded dependencies and monolithic schemes are used. The tools can be extended and used for a wide range of projects, the editor itself being quite agnostic to the game type and even the engine used. The solution presented here can be implemented in many ways, from the command system interfaces to the UI or plug-in system. In all cases, one thing remains constant: the use of UI-independent editing operations is separated from the tools' GUI using the command layer. I hope this article inspires you to make the right choices when creating extensible, elegant solutions for your game development tools.

Definition

3D human reconstruction is an important research topic in VR/AR content creation, virtual fitting, human-computer interaction, and other fields. Deep learning theory has made important achievements in human motion detection, recognition, tracking, and other aspects, and human motion detection and recognition is an important link in 3D reconstruction. In this entry, the deep learning algorithms in recent years, mainly used for human motion detection and recognition, are reviewed, and the existing methods are divided into three types: CNN-based, RNN-based, and GNN-based. At the same time, the main stream data sets and frameworks adopted in the references are summarized. The content of this entry provides some references for the research of 3d reconstruction of human motion.

Introduction

The earliest study of human movements was proposed by Johansson (1973). The motion of the main joints is described by a few bright spots

against a dark background. The effectiveness of the kinetic-geometric model for visual vector analysis is verified. This study opens the door for human motion analysis. Since almost all human behavior understanding needs to be based on accurate motion reconstruction, human motion reconstruction is a hot topic in the field of computer vision. At present, the 3D reconstruction technology of human motion has been widely applied in human-computer interaction, costume design, virtual fitting, and games.

From the technical point of view, there are many deep learning algorithms for 3D reconstruction of human motion detection, and different algorithms have different processing methods. Based on the standard RNN model typically used for human motion, Martinezet et al. (2017) develop a sequence-sequence model with residual connections. Its performance is better than the early human motion prediction work and achieves good results. Li et al. (2020) propose a dynamic multi-scale graph neural network (DMGNN) which is adaptive during training and a multiscale graph computational unit (MGCU). Despite the continuous improvement of deep learning algorithms, motion pose estimation has been a recognized problem for researchers in the study of computer vision. A good attitude estimation method needs to be robust to occlusion and deformation, stable to changes caused by factors such as illumination and clothing, and the human body is a hinged object with different attitudes, so it is difficult to keep absolute static.

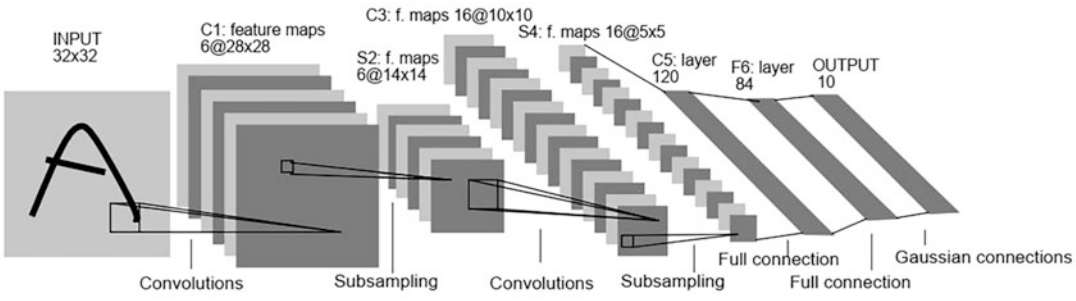
This paper reviews the 3D reconstruction of human motion detection based on deep learning algorithm. Firstly, the foundation of deep learning algorithm is introduced in detail. Then, according to different reconstruction methods, the latest research progress is introduced from two aspects of direct reconstruction and two-stage reconstruction. Finally, the framework of deep learning and the data set used in the research literature are introduced.

D

Deep Learning Fundamentals

For different types of data and problems, people have studied all kinds of neural network structural models. Now, the mainstream methods of deep learning technology in 3d reconstruction of human motion detection are mainly CNN, RNN, and GNN as the basic framework or their combination, and has achieved remarkable results.

Figure 1 shows the overall structure of convolutional neural network, which is mainly composed of convolution layer, activation function, pooling layer, and full connection layer. LeCun et al. first proposed Convolutional Neural Network (CNN) in 1998 (LeCun et al. 1998). The structure of LeNet network is divided into eight layers, which mainly uses the principle of image local correlation to process image data. AlexNet is a Convolutional Neural Network developed by Krizhevsky et al. In the ILSVRC competition of that year, the error rate of Top5 is reduced to 15.315%. Compared with Lenet-5, AlexNet uses a deeper network structure, with 5 convolution layers, 3 full connection layers, 60 million parameters, and 65,000 neurons. AlexNet uses two Gpus for calculation, which greatly improves the computing efficiency. The sigmoid function and Tanh

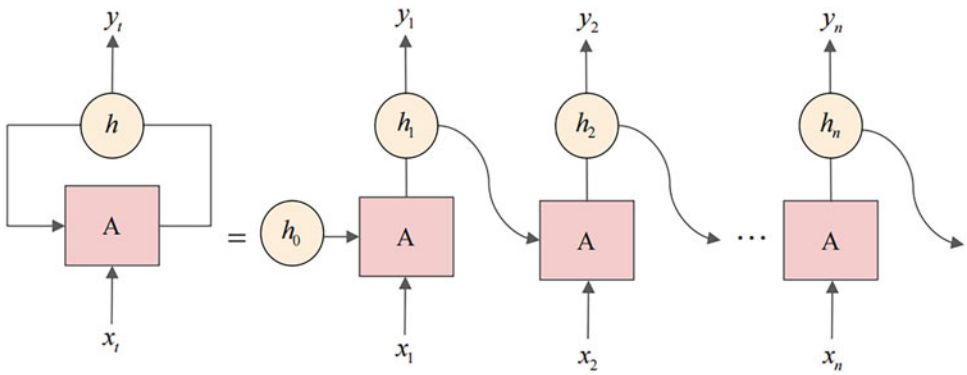


Deep Learning Algorithms for 3D Reconstruction, Fig. 1 Schematic diagram of CNN (LeCun et al. 1998)

function are replaced with the non-saturated nonlinear function ReLU function (Krizhevsky et al. 2012). Since AlexNet, deep learning has enjoyed a Renaissance. In the following years, various Convolutional Neural Network models based on the basic structure of AlexNet spring up, such as VGGNet, GooleNet, and ResNet (He et al. 2016). The proposal of ResNet is an improvement on the degradation of deep network structure, which is a milestone event in the history of CNN image processing. Since then, the research focus of the academia has changed from how to improve the accuracy of the neural network to how to achieve the same accuracy with less parameters and calculation. SqueezeNet is a typical example (Iandola et al. 2016). With the deepening of deep learning research, more CNN models and design ideas have been adopted into the network model design of 3D human motion reconstruction, which greatly promotes the development of 3D human motion reconstruction technology.

RNN (Recurrent Neural Network) is used to process sequence data. The difference between CNN and RNN is that a directional loop is formed between neurons, in which the hidden state at the last moment and the input at this moment are both the input of neurons, so the network can remember the information at the previous moment. The structure of circulation unit is shown in Fig. 2. RNN is unidirectional propagation. Based on this, bidirectional RNN (Schuster and Paliwal 1997) is proposed. In the process of training RNN, due to the repeated multiplication of weights, the problems of gradient disappearance and explosion are easy to occur, and it is difficult to learn for a long time. Therefore, RNN can only deal with the problems of short sequence dependence. LSTM (Hochreiter and Schmidhuber 1997) is an improvement on RNN. Different from the cyclic layer in the basic structure of RNN, LSTM uses a gate control mechanism in the memory unit and combines short-term memory with long-term memory. It can learn the content with long time dependence and alleviate the problem of gradient explosion and disappearance to a certain extent. GRU is improved on the basis of LSTM. It has the same effect as LSTM, but it is improved in structure. GRU (Cho et al. 2014) simplifies the three "gates" of LSTM structure to two "gates". To prevent the gradient from disappearing and exploding, IndRNN (Li et al. 2018) introduces Relu as the activation function, and separates the neurons in the layer, which can also build a deeper and longer network and make the network learn for a long time. Dual-path Recursive Neural Network (DPRNN) (Luo et al. 2020) is an effective and simple way to organize RNN layers in deep structures to make RNN model long sequences. The experimental result shows that replacing one-dimensional CNN with DPRNN in TasNet can improve the experimental results (Fig. 3).

Scarselli et al. (2008) first proposed the concept of graph neural network in their entry. In the entry, they used neural network on graph structure data. GNN also has many limitations and is suitable for shallow structures, most with no more than three layers. Graph Convolutional Neural Network (GCN) (Kipf and Welling 2016) summarizes the convolutional operation from grid data to graph data, which is a combination of CNN and



Deep Learning Algorithms for 3D Reconstruction, Fig. 2 Schematic diagram of RNN (Schuster and Paliwal 1997)

graph topology structure, and implements multi-layer stacking. When constructing GCN, two methods, spectral method and non-spectral method, are usually followed. The Graph Attention Network (GAT) (Busbridge et al. 2019) introduces the attention mechanism based on GCN. Masked self-attentional layers is introduced to improve the disadvantages of graph convolution. Assigning corresponding weights to different adjacent nodes requires neither matrix operation nor prior knowledge of the graph structure. The model has better performance and is more robust to disturbances. Relational Graph Attention Networks (Busbridge et al. 2019) applies the Attention mechanism to graph convolution and adds relational information to the model, thus extending the non-relational graph attention mechanism. Relational Graph Attention Networks is an extension of GAT and has broader applications. Aiming at the problems of GCNs, Self-Supervised Semantic Alignment for Graph Convolution Network (SelfSAGCN) is proposed. Identity Aggregation and Semantic Alignment are its two key approaches. This algorithm reduces over-smoothing and enhances the similarity between unlabeled features and labeled features of the same class. Experimental results show that the algorithm is better than other methods in various classification tasks (Yang et al. 2021).

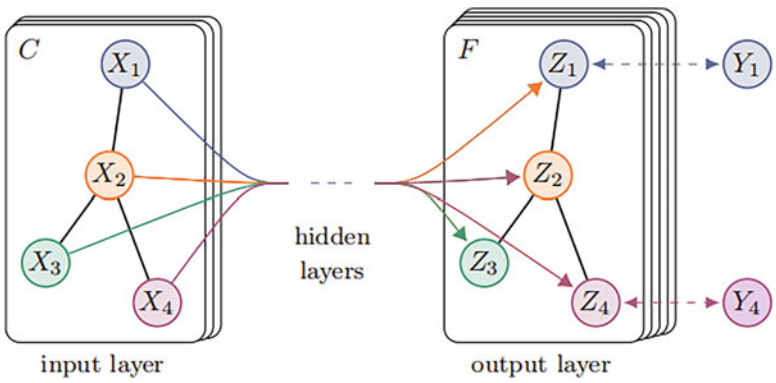
3D Reconstruction with Deep Learning

3D reconstruction of human motion detection is a very complicated process. As discussed earlier, the mainstream approaches to deep learning technologies have their own characteristics. Depending on the specific properties of these methods, how to apply these deep learning methods to 3D reconstruction of human motion is extremely important. Based on the types of deep learning methods, this section elaborates 3D reconstruction of human motion detection from the following three aspects: (i) CNN based, (ii) RNN based, human motion reconstruction.

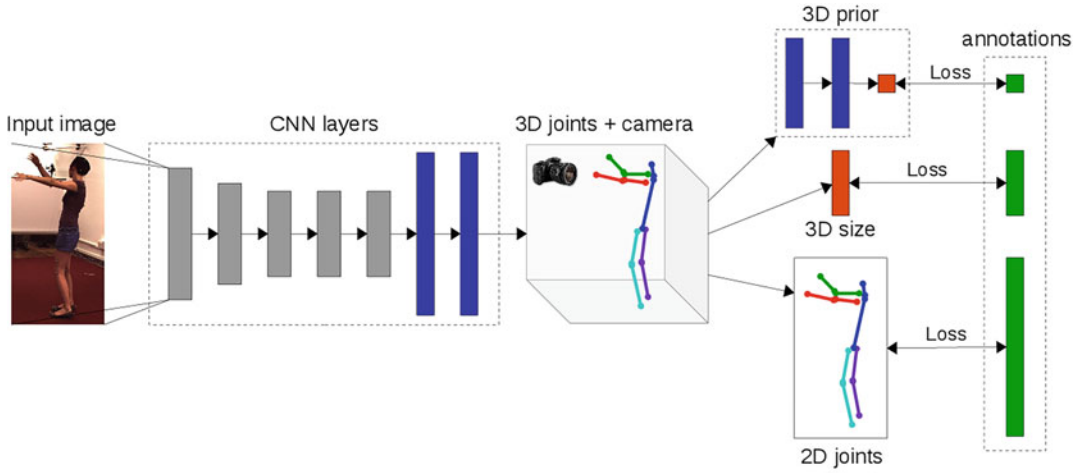
D

CNN Approach

CNN is the most widely used neural network among all the neural networks, and it is also the first one used for 3D reconstruction of human motion detection. It can process images and any kind of data that can be converted into a similar image structure. Tompson et al. (2014) propose to use CNN to make pose estimation and use heat map to regression the key points. The method optimizes the prediction results by using the structural relations between key points and markov random field. LeCun's team proposes a novel architecture in which refined models are cascered with the latest CNN models, including an effective "position refinement" model that can be trained to estimate joint offset positions in small areas of the image (Tompson et al. 2015). Stacked hourglass networks is a cascade of funnel-like neural networks, each of which acts as an encoder and decoder to extract features and generate heat map results (Newell et al. 2016). In recent years, many studies on human pose estimation (single or multiple) have been based on this basic network structure, as well as another network structure, OpenPose. OpenPose is an open source project at Carnegie Mellon University based on models



Deep Learning Algorithms for 3D Reconstruction, Fig. 3 Graph Convolutional Neural Network (Kipf and Welling 2016)



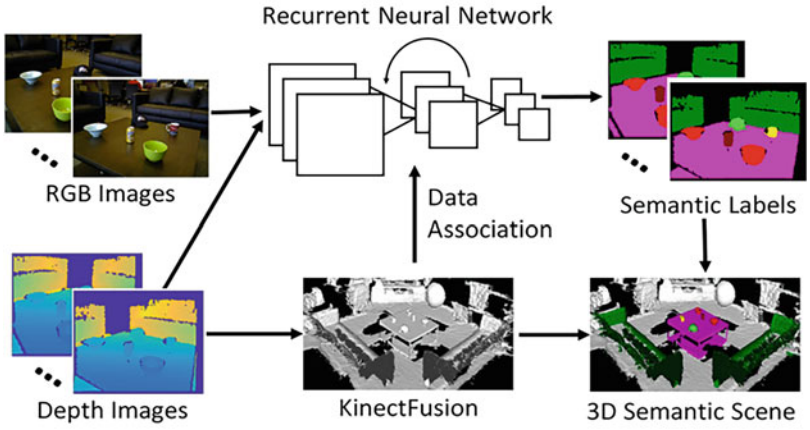
Deep Learning Algorithms for 3D Reconstruction, Fig. 4 Multi-Resolution Sliding-Window with Overlapping Receptive Fields (Brau and Jiang 2016)

from three papers. One of the papers (Cao et al. 2017) describes the 2D pose detection method PAF (Part Affinity Fields) in multi-player images, which first detects various points and then connects them with individuals to realize real-time detection of multiple people. Ke et al. (2018) improve the recent deep convolution and deconvolution hourglass model in four key points, and develop a robust multi-scale structural perceptual neural network for human pose estimation. Figure 4 shows deep learning architecture consists of three main components, a convolutional neural network (CNN), a camera projection and bone length computation layer, and a 3D pose prior network (Brau and Jiang 2016).

RNN Approach

The dynamic characteristics and context-dependent information of action can be captured by using recurrent neural network (RNN). Based on layered bone input, a multi-layer RNN framework is proposed by Du et al. (2019). In the algorithm, the human body is divided into five parts, and then each part is input into five subnets for training. In the end, the extracted features are input into a single layer perceptron to determine the action category. Based on the RNNs with Long Short-Term Memory (LSTM), an attentional mechanism is proposed to learn temporal and spatial features of skeleton data in human motion recognition tasks (Yang et al. 2020). In the attention subnetwork of spatial dimension, the author uses LSTM network to learn the relationship between the nodes of the current frame and the nodes of the previous frame, form a currently input attention map frame node data, and automatically find the current frame data of skeleton points, which has the greatest impact on action recognition. In the attention subnetwork of the time dimension, the author uses the LSTM network to learn the relationship between the current frame and the previous frame, to form the attention map of the current input frame data, and automatically learn which video frames contribute the most to action recognition. Zhang et al. (2017) propose an adaptive recursive neural network (RNN) based on LSTM structure, instead of relocating the skeleton based on human defined prior criteria. This allows the network itself to adapt from one end to the other to the most appropriate point of view. Xiang and Fox (2017) integrate DA-RNN's with KinectFusion (Newcombe et al. 2011) for semantic 3D scene reconstruction. KinectFusion was known as an accurate real-time mapping of indoor scenes in variable lighting conditions (Fig. 5).

Multistage convolutional neural network (CNN) has made advanced achievements in realizing single image human posture estimation, but



Deep Learning Algorithms for 3D Reconstruction, Fig. 5 The pixel labels provided by the RNN are integrated into the 3D semantic map (Newcombe et al. 2011)

its application to video requires a lot of calculation, and there will be performance degradation and jitter. A new recursive LSTM model is proposed for video pose estimation (Luo et al. 2018). Artacho and Savakis (2020) proposed UniPose and Unipos-LSTM architectures for single image and video pose estimation respectively. This structure can better understand the context information in the framework and help to estimate the posture of the subject more accurately.

Definitions

Deep learning (DL) is a special type of machine learning (ML) (Yu et al. 2012; De et al. 2018) in which an artificial neural network (ANN) is utilized to map a set of input parameters into a set of outputs. DL works with labeled datasets as training samples which usually involve complex, high-dimensional raw input data (Lou et al. 2018). It needs less manual feature engineering than prior ML methods (Liang et al. 2018). DL has enabled significant progress in many application fields such as computer vision, games, and virtual and augmented reality (Khiew et al. 2019).

In artificial intelligence (AI) game designs, behavior of the in-application non-player character (NPC) is a key issue. It will largely affect the overall quality of the game user experience. Instead of designing specific NPC algorithms, the NPC agent can be trained with reinforcement learning (RL) in the entire behavior system by configuring the desired game environment and a set of hyperparameters. RL is conceptualized as a Markov decision process (MDP). Refer to Fig. 1, an Agent at an execution step t is defined by a State S_t. The Agent arbitrarily takes an Action A_t, which results in a change of the Environment. The Environment provides the Agent with a feedback Reward/Penalty score R_{t+1} for its next execution

step $t + 1$, and transits the Agent to next State S_{t+1} according to the environment dynamics. In a trial-and-error manner, the Agent attempts to learn a policyfrom observations to actions, in order to maximize/minimize its expected sum of Reward/Penalty scores.

In practice, an RL policy is dependent on a high-dimensional vector of inputs. Deep reinforcement learning (DRL) is to implement a DL network with an RL policy. In this study, DRL is to solve the problem of an NPC learning to make decisions in the AI game. In particular, DRL allows an NPC agent to make decisions from high-dimensional and unstructured input data without manual engineering of the state space. The implemented DRL algorithms are able to take in a very large set of inputs, for example, all pixels in a video game, and decide what actions to take to optimize an objective, for example, maximizing the game score.

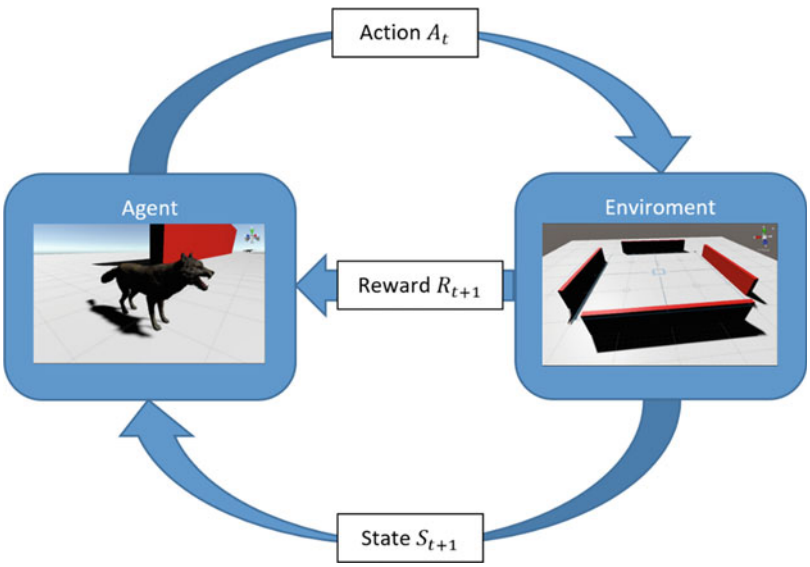
Applications of Deep Reinforcement Learning in Virtual Reality

DRL proves to be a promising tool for real-time feedback to virtual reality (VR) and intelligent virtual environments (IVE) (Wang et al. 2019a, b, 2020; Kumar et al. 2016; Liu et al. 2020). In the applications, DRL ANN is implemented with a specific reinforcement learning policy according to the problems to be solved. A machine learning agent is rewarded for actions that achieve the target outcome and penalized if not. The DRL applications in two case studies are demonstrated.

Case Study 1

The conventional agricultural unmanned aerial vehicle (AUAV) is based on the principles of aerodynamics and atmospheric turbulence, and its flight control system involves a complex process and needs a long learning curve. It requires the operators to be familiar with the aerodynamic characteristics of the AUAV, as well as the agricultural tasks such as spraying; the operators have also to be vulnerable to external meteorological and geographical environments which are constraint by the climate conditions; and worse, failures in the operations often lead to crashes of the drones, which is costly.

To largely reduce the dependence on the physical settings for the AUAV tasks, with references to our other VR autonomous movement controls (Zhao et al. 2021a, b) and path finding algorithms (Zhang et al. 2021a), DRL is applied into a VR AUAV. Modeling based on our four-rotor AUAV,



Deep Reinforcement Learning in Virtual Environments, Fig. 1 Reinforcement learning for an agent to adapt to the environment

and targeting at complex external meteorological and geographical environments as well as irregular plants, the VR AUAV flight is simulated and controlled using its machine learning agent. Briefly,

(a) A momentum balance model (MBM) of four-rotor AUAV and its intelligent runtime control system is designed.
(b) Virtual flight controls of the four-rotor AUAV by graphical user interface (GUI), including take-off, landing, forward flight, left/right turn, are implemented with its flight parameters for optimization in real time.
(c) DRL for the roam function is implemented to acquire the flight attitude and position information of the drone, as well as simulation of the control of agricultural spraying and sowing with particle systems, a VR simulation shown in Fig. 2.

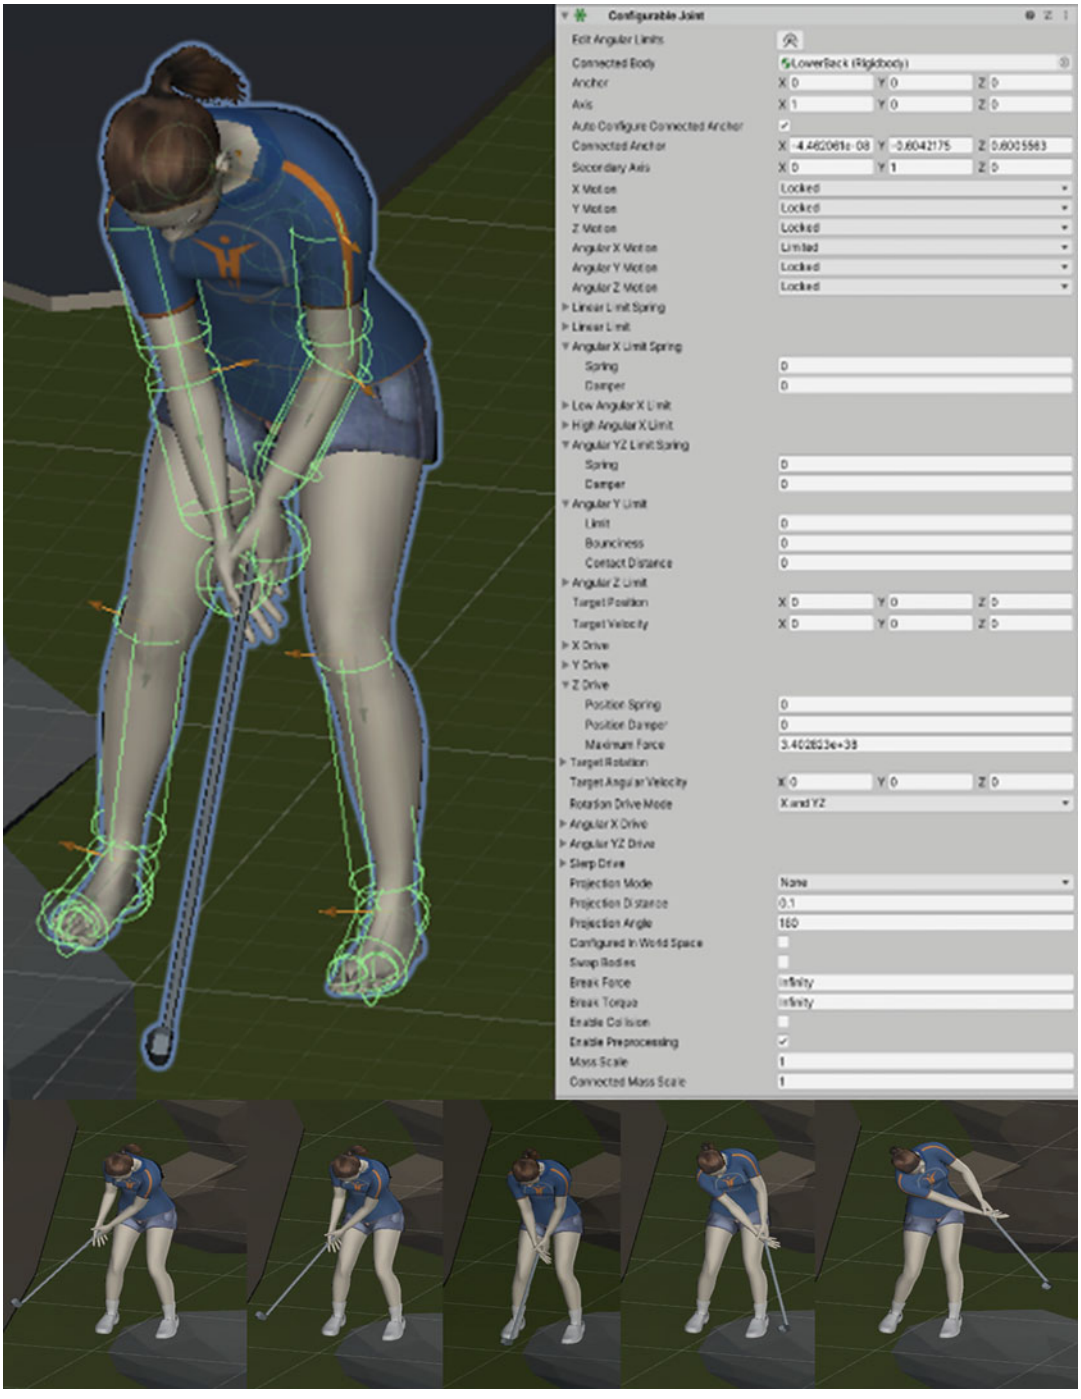
Case Study 2

A VR golf training environment is designed, with two humanoid avatars, one representing the trainer and the other for the machine learning agent. Configurable joints and rigid bodies are added to the body parts of the humanoid avatar, as shown in Fig. 3 (upper). This allows for physics to be added to the character as well as movements of the character to be customized by configuring the X, Y and Z motion and angular motion of each body part (Wu et al. 2004; Cai et al. 2016, 2017). By locking or limiting certain X, Y, and Z motion and angular motion, it prevents the joints from moving erratically in the VR game.

In the DRL processes for the VR game, as shown in Fig. 3 (lower), the humanoid agent acts based on the observations generated and is given a reward correspondingly (Zhang et al. 2021b; Ming et al. 2021). The various attributes of the humanoid agent such as the number of actions to be taken are defined by the behavior component (Leong et al. 2020). Briefly,

(a) Before training is undertaken, the humanoid agent possesses a Learning Behavior where the attributes are undefined. At the end of the training session, an ANN file is generated. By attaching the trained ANN file to the humanoid agent, the initial Learning Behavior transfers into Inference Behavior and the attributes become defined.
(b) These attributes are passed on to the master controller which calculates the offset between the rotation, angular momentum, center of mass of the agent's body parts and trainer's body parts. The observations made by the master controller are used by the agent component to compute the corresponding reward.
(c) The difference in these values between the agent and trainer are tracked as observations. During training, the values can be seen from the master controller script attached to the humanoid agent. Through

Deep Reinforcement Learning in Virtual Environments, Fig. 2 DRL for VR AUAV flight controls in IVE of agricultural spraying



Deep Reinforcement Learning in Virtual Environments, Fig. 3 DRL for VR golf swing

RDL, the agent continuously makes decisions that will minimize the difference between these values.

(d) The reward function incentivizes the agent to move closely to the trainer's action. It is obtained by adding the respective reward earned from the observations made.

Conclusions

In the two case studies on VR applications, DRL has been proven to be effective for training intelligent and autonomous in-game agents. Nevertheless, while a virtual policy in RL is easy to realize compared with its counterpart in real-world, the virtual environments with complex physics are yet to be researched. This is critical in scenarios when precision of the agent is seen as the priority in the learning process (Zhao et al. 2021c). More robust and efficient reinforcement learning algorithms should be investigated for real-time systems of Virtual Reality and Intelligent Virtual Environments.

Definition

Delaunay Triangulation is a geometrical structure widely used in Computational Geometry. It was proposed by Boris Nikolaevich Delone (1890–1980) in 1934. Basically, given a set of n vertices $V(n)$ $(n \geq 3)$ a Delaunay Triangulation is a net of non-overlapping triangles whose set of vertices is $V(n)$.

Introduction

A triangulation is a connection of vertices by edges, which form a set of non-overlapping triangles (Sinclair 2016). The most known triangulations in the literature are: Greedy Triangulation (Dickerson et al. 1994), Triangulation of Garey (Garey et al. 1978), Radial Sweep (Hjelle and Dæhlen 2006), and Delaunay Triangulation (de Berg et al. 2008).

The Delaunay Triangulation for the set of vertices $V(n)$ satisfies four properties: (i) local-empty circle: for each circumcircle C_{ijk} created for a Delaunay triangle t_{ijk}, there is not any vertex v_l of other triangle falling inside the circumcircle C_{ijk} (de Berg et al. 2008), (ii) Maximize the minimum angles, (iii) a Delaunay Triangulation is unique (Verbree 2010), and (iv) the boundary of a Delaunay Triangulation for a set of vertices $V(n)$ is the convex hull of $V(n)$.

A Delaunay Triangulation has a dual graph called a Voronoi diagram, which is formed by using circumcenters of Delaunay triangles (or tetrahedra), thus some authors have taken advantage of this to explore both geometrical structures (Watson 1981; Chew 1990; Agarwal et al. 2015; Allen et al. 2016). The most common methods to construct a Delaunay Triangulation are Lawson method (Lawson 1977), Bowyer method (Bowyer 1981) and Watson method (Watson 1981).

For the set of vertices $V(n)$ shown in Fig. 1a, it is created a Delaunay Triangulation (see Fig. 1b). The convex hull for the set of vertices $V(n)$ is depicted in Fig. 1c. Whereas Fig. 1d depicted the circumcircles, and Fig. 1e shows the centers for each circumcircle. Finally, the Voronoi diagram is represented in Fig. 1f.

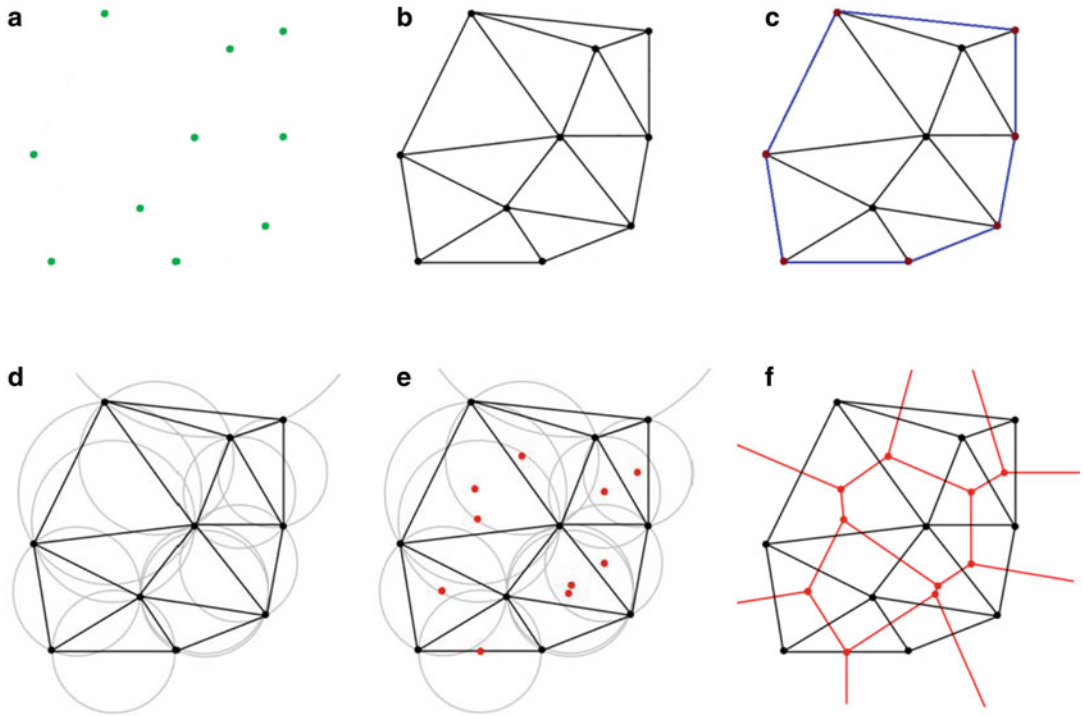
Properties

A Delaunay Triangulation has to satisfy four properties: Local empty circle, maximize the minimum angles, uniqueness, and boundary (convex hull).

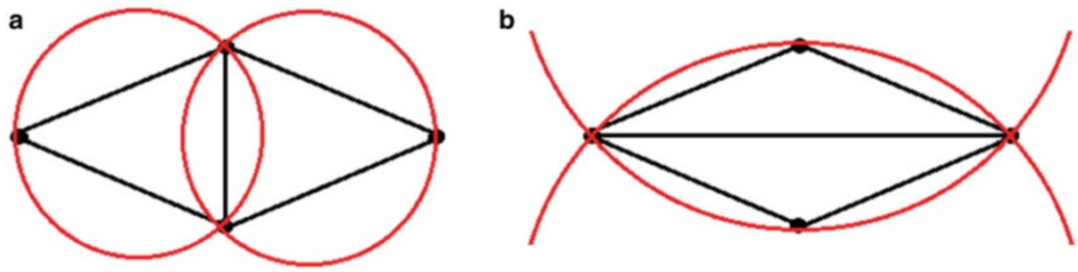
1. **Local empty circle**: A circumcircle is a unique circle passing through all vertices of a triangle in a Delaunay Triangulation $DT(V(n))$. This circle contains no other vertex from the set of vertices $V(n)$, (see Fig. 2) (van Kreveld 2014).

There are two levels to prove this property: (i) an edge e_{ij} is Delaunay if and only if there is not any vertex of the triangulation that falls inside the minimum circle that passes through both vertices of the edge. And, (ii) a triangle t_{ijk} is Delaunay if and only if there is not any vertex of the triangulation that falls inside the circumcircle of the triangle. A triangulation is Delaunay if and only if each edge or each triangle is Delaunay. Local Empty Property is shown in Fig. 2a, whereas Fig. 2b shown that the triangles does not satisfy the property.

Maximize the minimum angles: For each quadrilateral in Delaunay Triangulation *DT(V(n))*, two possible triangulations can be produced; the triangulation that maximizes the minimum of the six internal angles is the correct triangulation (see Fig. 3). It means, for each quadrilateral in a Delaunay Triangulation, there are two different triangulations with two triangles each one; let t_a and t_b be



Delaunay Triangulation, Fig. 1 Delaunay triangulation and voronoi (**a**) Delaunay Points (**b**) Delaunay Triangulation (**c**) Convex Hull (**d**) Delaunay Circuncircles (**e**) Delaunay Circumcenters (**f**) Voronoi Diagram



Delaunay Triangulation, Fig. 2 The local empty circle property (**a**) Delaunay Triangles (**b**) No Delaunay Triangles

triangulations. Let αt_a and αt_b be the smallest angle of the triangulations t_a and t_b, respectively. The Delaunay Triangulation includes the biggest angle between αt_a and αt_b (see Fig. 3b). For a Delaunay triangulation, Fig. 3a shows an invalid angles construction. A correct angle construction is depicted in Fig. 3b, which maximizes the minimum of the six internal angles (Mandal and Agarwal 2011).

Uniqueness: Delaunay Triangulation *DT(V(n))* is unique for a set of vertices *V(n)*, except for a set of four cocircular vertices (Khanimov and Sharir 2015) (see Fig. 4a). Similarly, Delaunay Tetrahedralization *DT(V(n))* is unique for a set of vertices *V(n)*, except for a set of five co-spherical vertices; for instance: a box (see Fig. 4b).

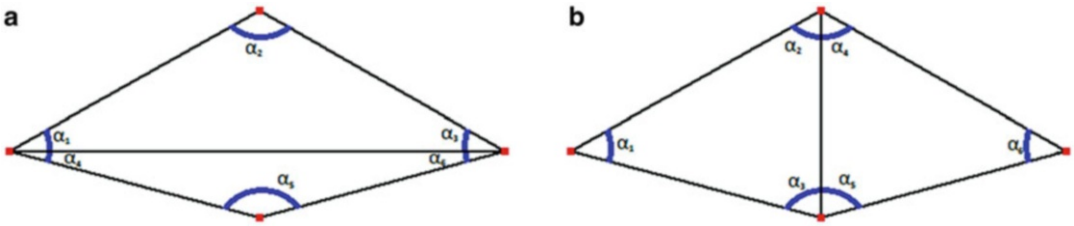
Those examples are based on regular shapes; however, irregular polygons or polyhedral can form a no-unique triangulation, for instance: uniform triangular prisms and uniform rectangular prisms, amongst others. Additionally, this exception can be extended to upper number of co-circular and co-spherical vertices.

Boundary: The borders of a Delaunay Triangulation *DT(V(n))* is the convex hull of *V(n)* (see Fig. 1c).

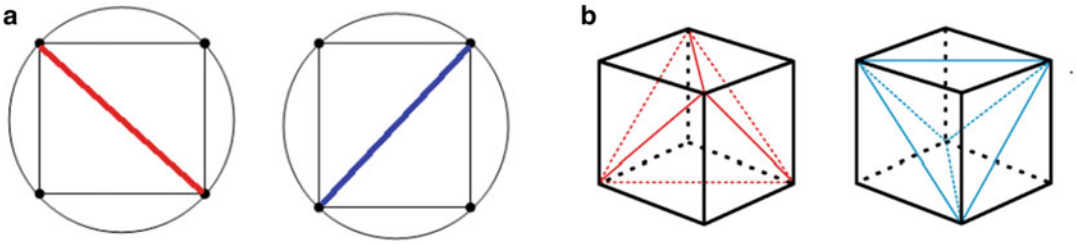
Quality in a Delaunay Triangulation

The following list shows a set of features that can ensure high quality in a Delaunay Triangulation (van Kreveld 2014):

- It does not have long edges. Long edges produce degeneracies; they are good in the boundary of the triangulation.
- It does not have triangles with both, short and long edges. The combination of long and short edges produces needles and caps.
- It does not have triangles with very small angles; these triangles can be needles or needle and caps.
- It does not have triangles with obtuse angles. Caps and needle and caps have these type of angles.
- It does not have vertices with high degree. A vertex connected to a high number of vertices is related with small angles, and, consequently, they are degeneracies.
- The combination of both long-short edges and small-obtuse angles produces degeneracies; it means needles and/or caps in two dimensions.



Delaunay Triangulation, Fig. 3 Bad and good angles in a Delaunay Triangulation (**a**) Bad angles in a Delaunay Triangulation (**b**) Good angles in a Delaunay Triangulation



Delaunay Triangulation, Fig. 4 No-unique Delaunay triangulation and tetrahedralization (**a**) No-unique Delaunay triangulation (**b**) No-unique Delaunay tetrahedralizations

Number of Triangles in a Delaunay Triangulation

According to van Kreveld (2014), a Delaunay Triangulation from n vertices – or a $DT(V(n))$ – have at least $n - 2$ and at most $2n - 5$ Delaunay triangles; moreover, it has at least $2n - 3$ and at most 3n − 6 Delaunay edges. According to de Berg et al. (2008) a Delaunay Triangulation from n vertices has $2n - 2 - k$ triangles and $3n - 3 - k$ edges, where k is the number of vertices in the Convex Hull.

Advantages of Delaunay Triangulation

The following list shows the main advantages of a Delaunay Triangulation (Mys 2004):

- It has elegant theoretical foundations and it has a wide range of application.
- The convex hull of the set of vertices is a part of a Delaunay Triangulation.
- The line connecting each point to its nearest neighbor must be in a Delaunay Triangulation.
- It produces a continuous surface, and it has an irregular connectivity.
- The construction does not depend on the starting point nor the dispersion of the points; it is predictable, repeatable, and equally easy (or hard) to construct for all applications.
- It is a method to cover a surface of a polygon using triangles.
- It is a common method to represent Triangulated Irregular Networks (TIN).
- It generates a mesh automatically.

Disadvantages of Delaunay Triangulation

Some disadvantages of working with Delaunay Triangulations include (Mys 2004):

- It does not maximize the minimum angle in three dimensions, even though, it does in two dimensions.
- When there is a mesh, the triangulation not always preserves it.
- It produces degeneracies in two and three dimensions.
- The type of tetrahedra with degeneracies in three dimensions is high (nine types) compared with degeneracies in two dimensions (three types).

Evaluation Tests

Even though Delaunay Triangulation has to fulfill the four properties described previously, the circumcircle criterion is the base of the evaluation of the structure; the circumcircle criterion forces the other properties.

The inCircle test verifies if a pair of adjacent triangles is Delaunay triangles; otherwise, the common edge between adjacent triangles has to be flipped to become a Delaunay triangles (Biniaz and Dastghaibyfard 2012). Similarly, the inSphere test proves the condition for a pair of tetrahedra; however, the change in the structure is not as straightforward as flipping an edge.

Let I be a set of indices and let $t_{ijk\ i,\ j,\ k \in I;\ i \neq j;\ i \neq k}$ be a triangle in counter-clockwise (CCW) orientation in the plane. Let C_{ijk} be the circumcircle of the triangle t_{ijk}. Let $v_l\ l \in I - \{i, j, k\}$ be a vertex. Then, the inCircle test is defined as follows:

$$\text{inCircle}\left(\tau_{ijk}, \vartheta_l\right) \begin{cases} = 0; & \vartheta_l \in C_{ijk}.\left(\vartheta_l \text{ falls on } C_{ijk}\right). \\ > 0; & \vartheta_l \text{ is outside } C_{ijk}. \\ < 0; & \vartheta_l \text{ is inside } C_{ijk}. \end{cases}$$

In general, the inCircle test can be simplified in an operation as follows:

$$\text{inCircle}\left(\tau_{ijk}, \vartheta_l\right) = \begin{vmatrix} x_i & y_i & x_i^2 + y_i^2 & 1 \\ x_j & y_j & x_j^2 + y_j^2 & 1 \\ x_k & y_k & x_k^2 + y_k^2 & 1 \\ x_l & y_l & x_l^2 + y_l^2 & 1 \end{vmatrix}$$

The orientation test verifies the order of the vertices that define the triangle, it means, to calculate a Delaunay Triangulation, a circumcircle test is required; however, the triangle has to have a positive orientation (counter-clockwise orientation). The orientation test is given by the following expression:

$$\text{orientation}\ \ 2D\left(\tau_{ijk}\right) \begin{cases} = 0; & \text{the vertices are collinear.} \\ > 0; & \text{the triangle } \tau_{ijk} \text{ has a positive (CCW) orientation.} \\ < 0; & \text{the triangle } \tau_{ijk} \text{ has a negative (CW) orientation.} \end{cases}$$

where

$$\text{orientation}\quad 2D(\tau_{ijk}) = \begin{vmatrix} x_i & y_i & 1 \\ x_j & y_j & 1 \\ x_k & y_k & 1 \end{vmatrix} = \begin{vmatrix} (x_i - x_k) & (y_i - y_k) \\ (x_j - x_k) & (y_j - y_k) \end{vmatrix}$$

Conclusion and Discussion

A Delaunay Triangulation is a triangle net in which every triangle satisfies the Circumcircle condition: the circumcircle of each triangle includes only the vertices of the triangle. In other words, the circumcircle does not contain any vertex of other triangles. If both the inCircle and the Orientation tests are the algorithmically mannered to probe this condition for all the triangles in a triangulation, then it can be labelled as Delaunay Triangulation.

Definition

Learning analytics is defined as the measurement, gathering, analysis, and reporting of data about learners and their environments, for the aim of understanding and improving learning process and the contexts in which learning occurs (Siemens and Baker 2012).

Introduction

The technology era has been growing very quickly, and it leads to the new industrial revolution which is also known as Industry 4.0. The inventions of new technologies like virtual reality, 3D printer, and the Internet have greatly influenced different sectors of the world economy. The digital technology sector in the UK has grown tremendously despite the economic crisis in 2008. Based on the Tech Nation Report in 2018, the UK digital tech sector is worth nearly £184bn to the economy, a rise from £170bn in 2016 (Cahill et al. 2018). However, Job Market Report 2017 has shown that the growth of the digital economy and the emergence of new technologies has led to skills shortages and increased demand for graduates with the right qualifications (Dice 2017).

These advancements led educational institutions to be interested in possible changes that could involve the changes in curriculum which can help prepare the students to face the industry after they graduate. Industry 4.0 implies that the world is globalized, automatized, virtualized, networked, and flexible. This section briefly maps the education with industrial revolution. It is believed that education has to follow the pace of industrial revolution. The following section maps the education with industrial revolutions.

Mapping Education with Industrial Revolutions

The evolution of the industry which progresses from First Industrial Revolution (Industry 1.0) to Fourth Industrial Revolution (Industry 4.0) can be used as a sign to show how important it is that education should also be developed and evolved from Education 1.0 towards Education 4.0. The industry has undergone a process of digital transformation which exposes the education to challenges and opportunities of meeting the needs of the fast-growing industry. The changes in the industry development (industrial revolution) will also cause changes to the development of education (education revolution) which means certain

skills are required which are not exactly the same as the skills that were required before. Therefore, the current and future education structure should not only focus on training knowledge-based skill labor but also emphasize on cultivating innovative talent to meet the current demand of the industry.

Before and During Industry 1.0: Before the industrial revolution, education started by focusing only on teaching the elite classes and educating boys. Education was taught informally before it transformed by focusing on scientific research. Most education started with the dominance of religions. The industrial revolution caused widespread change in all aspects of society. Therefore, many motivated individuals could easily take advantage of the many economic opportunities of the situation. Research study also added in that modern economic growth depends on the growth of useful knowledge (Tang and Werner 2017). Therefore, this emphasizes the importance of gaining knowledge through education. Industry 1.0 marked the beginning of industrialization which led to the demand for mass education, education for ordinary people especially from lower classes. This was the time when there was a demand in the workforce fit for the industrial sector. More schools were built and the new concept "free education" was introduced during that period (Robinson 2011).

Industry 2.0: This industry began with electrification cycle when electricity became the primary source of power since twentieth century (Hughes 1993). During the Second Industrial Revolution (Industry 2.0), the graduates were viewed as ill-prepared line assembly workers as the inventions of machines helped a lot in mass production. Skill undoubtedly played an important role in technological innovation and adoption (Greenwood 1997). People did not know how to work efficiently until Frederick Taylor and Henry Ford proposed workplace methods and just-in-time and lean manufacturing principles to optimize the workforce and improve their quality and output.

Industry 3.0: It is also known as the information revolution or the digital revolution. This is the era of production automation when there is an increasing use of electronics in industrial process and commerce and computer-programmed electronic devices replaced the electric-based production machines (Khan 1987). The Third Industrial Revolution (Industry 3.0) initiated the telecommunication industry, and this implies that as communication became easier, people could access and create content anywhere, any time. However, there are some countries that are still applying the approach used in Education 1.0 which only involves one-way learning process (where students are passive and they are instilled with the most essential or basic academic knowledge and skills and character development (Petrina 1998; Gerstein 2014) and Education 2.0 (an approach used where students are active learners and gain knowledge by formulating and solving their own problems (McWilliam 2009; Gerstein 2014), while other countries have started developing new education models that reflect the increased use of technology and enable increasingly flexible, experimental, and fairer learning environments which lead to the introduction of the new era, Education 3.0. Students started sharing their knowledge with peers who have different skills and levels of knowledge to co-create new knowledge. This shows that technology was used to assist students' learning process and helped them in shaping the content, location, and ways in which they learn.

Industry 4.0: Due to the new industry era, the technology grows rapidly, and there are so many new inventions. However, Lortie (2002) argued that at the beginning of twenty-first century, the education does not change at a rapid pace as the structures of education are still the same as in the twentieth century. The existence of sensors and IOT can actually indicate an early sign of the use of wearables-assisted teaching, learning, and training devices. Recently, there is a limited number of research studies that use smartphones and sensors to study the factors that affect the academic performance of students. It was found out that there are many other factors that affect their performance, and this leads to complexity in research. As Education 4.0 indicates the world is complex, standardization approach that was used to be applied in Education 1.0 had to be eradicated. It is also added that standardized learning methods cannot deliver what the current and

future education needs when it comes to cope with complexity (Wallner 2012). This is true because everyone is different and unique, and everyone can stand out if one can manage to discover his/her own method of effective learning. This can be done through the assistance of current technologies invented in Industry 4.0.

The comparison between education evolutions and industry revolution are summarized in Table 1. The table shows that the technology advances rapidly, revolving from Industry 1.0 to the current era Industry 4.0, but the old educational models used in previous eras are still being applied in the fast-moving technology era. This implies that there is a gap between each education era and technology era. Education is moving slower than the industry. It has to move faster in order to catch up with the fast-growing demands, and in fact, it should be faster than the industry so that the supply of skills and talents can match with the demand of the industry.

Different Types of Analytics in Education

Learning analytics (LA) is a powerful tool which gives practical insights on the variables in the datasets. It focuses on the educational challenge in optimizing opportunities for learning. Siemens has first defined LA in his blog post as the use of intelligent data, learner-produced data, and analysis models to discover information and social connections and to predict and advise on learning (Siemens and Baker 2012). The definition was then refined in international conferences, and the Society for Learning Analytics Research (SOLAR) then defined LA as the measurement, gathering, analysis, and reporting of data about learners and their environments, for the aim of understanding and improving learning process and the contexts in which learning occurs.

LA is a new research field that is often associated with technology-enhanced learning. The improvement of teaching and learning using LA has led to the use of the term "Big Data" in the education field. Moreover, in this context, big data in education which is also known as educational data is what drives new methods to be used in LA (Siemens and Baker 2012). They stated that the specific features of data contributed to the different methods are playing a prominent role in educational data mining (EDM) and LA. LA is an emerging research field that studies strategies on how to enhance student and faculty performance,

Design Framework for Learning to Support Industry 4.0, Table 1 Summary of comparison between industrial revolution and education evolution

Types of revolution (Age)	Before eighteenth century (Agricultural Age)	Eighteenth century (Industrial Age)	Nineteenth century (Knowledge Age)	Twentieth century (Digital Age)	Twenty-first century (Connected World)
Industry	Before Industry 1.0	1.0 (Mechanization)	2.0 (Electrification cycle)	3.0 (Automation)	4.0 (Smart automation)
The views of industry on graduates	Industrial Age has not started yet	Assembly line workers	As ill-prepared assembly line workers	As co-workers	Lack of skills and talents as required (Evangelinos and Holley 2016; Manpower Group 2018)
Education	1.0	1.0 2.0 (Ideally)	1.0 2.0 3.0 (Ideally)	1.0 2.0 3.0 4.0 (Ideally)	1.0 2.0 3.0 4.0 (Still emerging)
Implication	–	There is a gap between each education era and technology era. Education is moving slower than the industry. It has to move faster in order to catch up with the fast-growing demands, and in fact, it should be faster than the industry so that the supply of skills and talents can match with the demand of the industry			

how to identify the needs of struggling learners, how to improve accuracy of prediction, etc. (Larusson and White 2014). In addition, LA helps to explore in what areas of the curriculum that can be improved. This complies with the definition of LA which is "the interpretation of a wide range of data produced by and gathered on behalf of students in order to assess academic progress, predict future performance, and spot potential issues" (Liñán and Pérez 2015). It can be clearly seen that there are different definitions provided for the term LA. However, these definitions focus on transforming educational data into actionable data to help improve the learning process.

The term academic analytics (AA) is always interchangeably used with LA. However, there is a distinction between these two terms. In order to identify the difference between LA and AA, it is vital to know the origin of AA. This term was first used to describe the business intelligence application tools and practices in higher education (Chatti et al. 2012). The authors further refer business intelligence to an analytics tool that involves the processes like collecting, storing, analyzing, and providing access to data to help enterprise users make informed business decisions. Therefore, to derive the definition from business intelligence and to place it in educational context, it can be said that AA is more emphasized on political or economic aspect of education as it helps to improve learning opportunities and educational results at institutional, regional, and international levels (Ferguson 2012; Daniel 2015). The author further added that AA benefits funders, administrators, marketing, government, and education authorities (Ferguson 2012). Like LA, AA also analyzes enormous data sets with statistical techniques and predictive modelling, but the purpose is to help in decision-making unlike LA which is used to help in improving learning process (Daniel 2015).

To narrow the definition down, AA focuses on student retention and graduation rates that actually affect the institutional level (Campbell et al. 2007). Issues of detecting students that are at risk are often related to AA (Chatti et al. 2012). In AA research, operational activities relevant to academic modules and student strengths and weakness can be identified and appropriately rectified.

Educational data mining (EDM) is a field which is often used together with LA as they present similar notions. However, both focus on different types of challenges. EDM deals more with the technical challenge while LA focuses more on educational challenge. EDM stresses on extracting value from an enormous pool of educational data. The phrase "data mining" in EDM has already suggested that it is very technical. It is concerned with developing methods to explore the unique types of educational data and identify the patterns in order to have a better understanding of the students and the environments in where they learn (Romero et al. 2010).

Quite similar to LA, the objective of EDM is to analyze the data to understand how students learn and to make predictions based on the analysis. Unlike EDM, LA further includes other methods, such as statistical and visualization tools or social network analysis (SNA) techniques and puts them into practice for studying their actual effectiveness on the improvement of teaching and learning. EDM focuses more on classification, association, and other data mining techniques in analyzing data.

It is hard to separate LA and adaptive learning analytics (ALA) because they both foster technology-supported, learner-centered education. LA is often associated with adaptation. Adaptation means making adjustments in a particular environment to accommodate the individual differences. Adaptivity and adaptability are the common terms that are related to adaptation. Adaptivity refers to a process where the data about learner is used in a system controlled way, whereas adaptability means the system supports end-user modifiability providing student control (Mavroudi et al. 2018).

A common idea behind those adaptive educational systems is that, based on the information about the learner and the current context, an appropriate adaptation method should be chosen to adapt the presentation of the course material to the individual learner. ALA focuses on learner modeling as the core for achieving adaptive and

personalized learning environments, which will be able to consider the heterogeneous needs of learners and provide them with tailored learning experience suited for their unique needs.

Motivation to Learn

Conventional educational pedagogy which adheres to the "one-size-fits-all" approach characteristic of traditional education systems can no longer be used in this fast-changing era. The motivation and capacity to learn independently is crucial to personalization which is the pedagogy for Education 4.0, because it reduces dependence on the teacher and traditional class-based styles of instruction. In order to produce individuals that thirst for learning, self-reflection and motivation are required to be reinforced (Leadbeater 2008). In addition, an education model will tend to undermine the possibility of independent learning and developing skills if there is a lack of motivation, because it can lead to a decrease in the levels of learning (Saveedra and Opfer 2012). As it is important to foster motivation for independent learning, research emphasizes the importance of the teacher's role in motivating learners and finding ways for them to build intrinsic motivation (Meyer et al. 2010). There are a few theories which contribute to the learning motivation of learners. Social cognitive theory reflects the importance of the relationship between behavior, environment factor, and personal factor as these three factors are interconnected, and it is also known as cause and effect relationship (Bandura 1989). This theory also depicts what caused the people to behave certain ways and provides basic interventions (Bandura 1997). It is also found out that environment factor can influence people and can be divided into social environment (family and friends) and physical environment (comforts) (Bandura 1997). These factors are also known to affect the students' learning process.

Research also found that the challenge, curiosity, control, and fantasy are the key factors to trigger up intrinsic motivation (Ryan and Deci 2000). These factors can boost will power and positive attitude in pursuing education. Moreover, Lepper et al. (2005) and Pérez-López and Contero (2013) claim that academic achievement also influences the intrinsic motivation. Attitude in learning is considered very essential as it influences the academic achievement (Cai et al. 2017).

Big Data Analytics, Academic Analytics, Learning Analytics Process

Big data analytics (BDA) in the education context is also known as LA. LA is more specific and only used in educational context, whereas BDA can be applied in different sectors. Thus, the stages involved in BDA are a bit different from the stages involved in LA and AA.

Data Collection and Pre-processing: The first stage in BDA, LA, and AA processes involves collecting a vast amount of data. In LA and AA, data are collected from the various educational environments and systems, whereas data in Big Data can be collected from different sources and they are not necessarily sourced from the educational context (Daniel 2015). These data often come in various attributes and formats. Researchers need to first determine the format of data, the amount of data to be used, and choose techniques to retrieve that data (Campbell et al. 2007).

As the collected data are available in vast amount, data have to be managed and pre-processed. These data are analyzed to discover interesting and useful patterns that can be used to retrieve useful information. In LA process, data is transformed into suitable format by using different methods such as data cleaning, data integration, data transformation, data reduction, data modelling, user and session identification, and path completion.

Statistics tools are recommended to be used during this stage to handle large quantities of data (Chatti et al. 2012). This stage is vital when it comes to computing the description for the data as it gives the end users a reflection on what has happened.

Analytics and Actions: The next stage of the process in LA, AA, and BDA is known as

analytics. Each technique used to analyze data depends on the type of selected data and the goal of the research. Different LA techniques like data mining techniques, statistics and mathematics, text mining, semantics and linguistic analysis, visualization social network analysis, qualitative analysis, and gamification can be applied to analyze and explore the data in order to discover hidden patterns or insights that can help to provide a more effective learning experience (Khalil and Ebner 2016).

The following stage in all three LA, AA, and BDA processes includes actions on the information that have been analyzed such as monitoring, analysis, prediction, intervention, assessment, adaptation, personalization, recommendation, and reflection. Taking actions is the primary aim of the whole analytics process (Daniel 2015) which also means answering questions that leads to the stage of data collection (Campbell et al. 2007). A model is built at the end of this stage and improvements can be seen as the result. These actions can be executed either manually or automatically which may include linking, connecting correlating different data sets to be able to obtain insight that is supposed to be conveyed by these data. In LA process, actions can be prescriptive as it can help students to be successful (Khalil and Ebner 2016). On the other hand, the complexity of BDA occurs when the management and the analysis of the largely diverse data becomes a complex process (Daniel 2015).

Refining/Post-processing/Visualization: The last stage of LA and AA processes is a bit different from the last step in BDA process. The last step in the BDA process actually involves presenting the analyzed data into an interpretable and integrated information to help inform the decision of stakeholders (Daniel 2015), whereas the last stage of LA and AA process includes continuous improvement of analytics exercise (Chatti et al. 2012; Campbell et al. 2007). This stage takes place when the actions taken in the previous stage and the processed results are evaluated. As stated in Chatti et al. (2012), this stage may include compiling new data from additional data sources, improving the data set, determining new criteria required for the new iteration, identifying new predictors or criteria, modifying the variables of analysis, or selecting a new analytics method.

Existing Frameworks

LA Framework: Previous literature studies have proposed different frameworks for LA. A reference model for LA is proposed based on four dimensions, namely, data and environments (what?), stakeholders (who?), objectives (why?), and methods (how?) (Chatti et al. 2012). Based on the reference model, various challenges and research opportunities are suggested by reviewing recent publications on LA and its related fields based on the proposed reference model. Findings showed that (1) centralized web-based learning systems represent the most widely used data source for LA, (2) most of the current LA applications are oriented toward intelligent tutors or researchers/system designers, (3) the most commonly applied objectives are adaptation and monitoring/analysis, and (4) the most frequently used LA techniques are classification and prediction.

The authors that proposed the generic model actually extended the reference model by adding two extra dimensions which are the external limitations and internal limitations (Greller and Drachsler 2012). The authors also argued that the critical problem zones, and some potential dangers to the beneficial exploitation of educational data, should be explored in order to provide a more comprehensive and useful guide for setting up LA services to support the learners, teachers, and institutions.

While the other proposed frameworks are only focusing on LA generally, a different framework that combines adaptation and LA was proposed and considered the same dimensions as the previously mentioned frameworks (what, who, why, and how) but added two more dimensions which are when and where (McWilliam 2009). This framework suggested the following points: (1) key data related to the context and tools used, (2) objectives, (3) stakeholders, (4) application area and context, (5) time-related aspects, and (6) use of LA and adaptation.

DigComp Framework and EntreComp Framework by European Commission: DigComp framework is a framework that consists of five dimensions which are competence areas, competences, proficiency level, examples of knowledge skills and attitudes, and example of applicability to purpose (Ferrari 2013). The competence areas which include information, communication, content creation, safety, and problem-solving are the main components of this framework (Vuorikari et al. 2016). This framework is being applied in the education sectors and proven to be helpful in investigating the digital attitudes, skills, and development needs of healthcare students (Evangelinos and Holley 2016). Besides that, this framework is also used to examine factors predicting lower secondary school students' digital competence (Hatlevik et al. 2015). This framework also covers three different proficiency levels and specified indicators for the development of each digital competence.

Similar to DigComp framework, EntreComp framework is also developed by the European Commission to establish a bridge between the world of education and employment and to be used as a reference by any initiative which aims to encourage entrepreneurial learning. Like DigComp framework, EntreComp has competence areas which are ideas and opportunities, resources, and putting strategies into action. Each area includes 5 competences which sums up to 15 competences along an eight-level progression model (Bacigalupo et al. 2016).

Issues Concerned with Existing Framework: There are several concerns that should be taken into consideration when it comes to designing LA. Researchers will also need to investigate problems faced by learners in different environments and what success looks like from the perspective of learners (Ferguson 2012). The analytics process should be transparent so that the learners can respond with feedback that can be used to refine the model and to be able to see how their data are used. The other researchers also added that LA can only be effective if the outcome can generate insights into the pedagogical didactic consequences for both learning and teaching practice (Ferguson 2012; Van den Bogaard and De Vries 2017). LA should be designed based on theoretical models and needs of students should be well understood. Feedback of LA is essential for learning, and it is important to identify which kind of feedback is suitable for which kind of student.

Feedback of LA leads to the question on the quality assurance of LA. The quality assurance of LA services is questioned as they might only meet the expectations of certain stakeholders (e.g., managers) while overlooking those who are the most important (e.g., students) (Liñán and Pérez 2015).

Although DigComp framework is being widely used for strategic support for policy making by European Union member, none has displayed strategies that can be used with different stakeholders to develop digital competence especially in the aspect of problem-solving (Balula 2016). The author also said that it is vital to highlight that DigComp framework is descriptive rather than prescriptive, and therefore, this framework is always prone to be revised and updated, and each update takes a long time as it involves many stakeholders to reach a consensus. EntreComp framework has not yet been adapted to or tested in real settings, and it is a result of a robust research methodology which involves experts' consultation and input. Therefore, it will also take time for the framework to be updated. A framework that suits education and industry needs should be able to be updated quickly to suit the needs as education evolution has been in a slow pace while technology is growing very rapidly (Table 2).

Conclusion and Discussion

There are studies on LA framework, but there is a limited number of studies (prior to our knowledge) focusing on students' motivation in learning in the design of LA framework. Attitude is important because the quality of framework will not even matter if the students do not have motivation to learn. Therefore, the design of the framework should start from focusing on the learners' motivation to learn (attitude) before focusing on other

Design Framework for Learning to Support Industry 4.0, Table 2 Summary on the strengths and limitations of different frameworks

Types of framework	Strengths	Limitations
LA framework	Provide a more comprehensive and useful guide for setting up LA services to support the learners, teachers, and institutions which is believed to cover all related aspects: (1) key data related to the context and tools used, (2) objectives (3) stakeholders, (4) application area and context, (5) time-related aspects, and (6) use of LA and adaptation	Quality assurance (only meet the expectations of certain stakeholders)
EntreComp framework	Used as a reference by any initiative which aims to encourage entrepreneurial learning	Has not yet been adapted to or tested in real settings and it is a result of a robust research methodology which involves experts' consultation and input
DigComp framework	Helpful in investigating the digital attitudes, skills, and development needs of students Used to examine factors predicting students' digital competence	This framework is always prone to be revised and updated, and each update takes a long time as it involves many stakeholders to reach a consensus

elements to help improve their learning process. To date, the education analytics such as LA, EDM, and so on have focused predominantly on analyzing data systematically gathered in educational settings, which at the tertiary level includes factors of prior academic performance, demographic data, such as age and gender, and data gathered by logs recording student behavior in online learning environments. Although the initial results in the literature studies are encouraging across a variety of analysis techniques, there is scope for more research investigating the contribution of additional data such as psychometric data that could be gathered by tertiary education providers, as well as how this data should be modelled to enhance the current algorithmic models of student learning, and offer actionable feedback on the learning process. Therefore, in order to address this issue, it is important to understand the factors that affect the students' learning progress so that more interventions can be done to help to solve the problems of talent shortage.

Design of Alienation in Video Games

Kemal Akay[1] and Cansu Nur Simsek[2]
[1]Unity Technologies, Copenhagen, Denmark
[2]Kadir Has University, Istanbul, Turkey

Synonyms

Alienation; Defamiliarization; Mechanics

Definition

In this entry, it is proposed that game designers can utilize hardware systems and the structure of gameplay to highlight a game's formal characteristics for "alienation" effect. Drawing inspiration from Bertolt Brecht's notion of "Verfremdungseffekt," or alienation effect, and using MDA framework (Hunicke et al. 2004), traits between alienation effect and techniques used in specific video games are analyzed to define what this article calls as "gamic alienation." Through the reading of gameplay moments in various games that make use of gamic alienation, a continuum that consists of two important concepts for creating this effect is identified: hardware signifiers and software signifiers. Throughout the entry, it is discussed how the use of these signifiers is implemented in a range of video games, from triple-A games such as *Metal Gear Solid* to indie games such as *DLC Quest*.

Introduction

In the area of video games, the player has similarities with the audience of a theatre play. The player is an active agent of the software, in which she provides the input, but concurrently, she is also the audience of play. The participatory structure of video games allows the players to become spectators of their own engagement with the system. This cyclic process of input and output can lead to changes in player's approach and behavior.

Playwright Bertolt Brecht argues that "The modern theatre mustn't be judged by its success in satisfying the audience's habits but by its success in transforming them" (Brecht 1964). A term coined by him, "alienation" is an effect that intends to disrupt the performative characteristic of a play to render the act of performance abnormal by underlining the conventions of the play, rather than its content. The goal is to raise self-awareness among the audience, make the theatrical devices visible, and as Brecht states, change the way an audience engages with a text.

According to Brecht, theater should attempt to stimulate social change by being provocative and didactic and also it should address their reason rather than their senses (Brecht 1991). Brechtian theater aims to break down the illusion of reality with the alienation effect which makes the audience critically aware of itself as audience and of the play as artifice. The audience is encouraged to observe their own daily circumstances in a new light.

When applied to video games, the concept of alienation can further enhance the quality of an audience's interaction with the medium (Dunne 2014). However, the studies between alienation effect and video games are not new to the field. For instance, it is known that horror game genre can use this effect to defamiliarize the player from the game; but with rare exceptions, the purpose is not to urge self-reflexivity, instead to convey specific aesthetic effects (Kirkland 2007). Therefore, it is important to acknowledge that the use of alienation effect may not always lead to critical play behavior.

Technical glitches, lags, and bugs can also be considered as alienating effects (Galloway 2006). In addition, loading screens or in-game interfaces such as pause screen or saving slots can be interpreted as mechanical systems that detract the player from core gameplay (Dunne 2014). However, that analysis is beyond the scope of this entry. It is important to acknowledge that this article examines "gamic alienation" that is intentionally constructed by game designers in order to break player's engagement with a game.

In this entry, the term alienation effect is not necessarily used in the political (i.e., Marxist

aesthetics) sense used by Brecht in his discussion of epic theatre. However, an emphasis is placed on the critical attitude that is aimed to encourage the audience (in this context, players) to adopt. In particular, formal game structures that are in the pursuit of inducing reflection in terms of aesthetics and refer to its own mechanics are highlighted. In that regard, this entry uses a pre-existing framework Mechanics, Dynamics, and Aesthetics (which will be referred to as "MDA") and by mechanics, "particular components of the game, at the level of data representation and algorithms" are meant (Hunicke et al. 2004). Aesthetics are defined as "the desirable emotional responses evoked in the player, when she interacts with the game system" and dynamics describe "the runtime behavior of the mechanics acting on player inputs and each others' outputs over time" (Hunicke et al. 2004). Thus, "gamic alienation" can be described as the technique in which the output of gameplay points out the mechanics of the game, and it is intrinsically designed for the purpose of encouraging reflection among players.

The rest of the entry is structured as follows. The terminology behind MDA framework in relation to "gamic alienation" is further explained. Then, two categories, namely, hardware signifiers and software signifiers, that demonstrate the ways game designers use alienation techniques are analyzed. These categories are explored with different examples. Finally, the entry shares its concluding marks and ends with suggestions for other works in future.

Mechanics, Dynamics and Aesthetics in Relation to Gamic Alienation

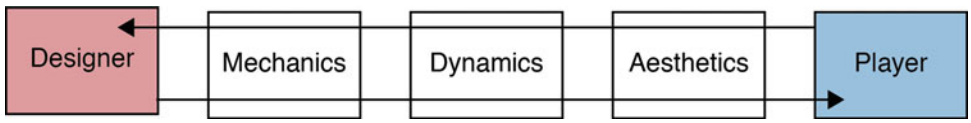
MDA framework provides a detailed terminology to analyze how each component influence designer's choices and influences player's experience. One of the objectives of MDA framework is to work as a bridge to close the gap "between game design and development, game criticism, and technical game research" (Hunicke et al. 2004).

In MDA, mechanics refer to formal aspects of game design, namely, set of rules, for instance, AI behavior, physics, winning condition, health system, etc., Dynamics is about how the game responds to actions player take during gameplay such as commanding an army, controlling a gang, fighting enemies, or simply navigational stuff like walking and running. All the rules have to work together and give proper feedback to the player. Aesthetics, on the other hand, defines player's experience and main interests in the game. For example, a player can start playing a game to get under the skin of a superhero, to beat a friend's high-score in a competitive game, or to enter a fantasy world.

The mechanics work in concert to make the dynamics, which generate the game's aesthetics (see Fig. 1). Game designers and players meet a game from the opposite sides. At a fundamental level, players start to experience a game through aesthetics and game designers initially construct their ideas with the mechanics, which in turn translates to player experience.

Similar to a playwright, a game designer can create the set of rules but has a little amount of control over how the act of play will be enacted by the players. In that regard, MDA framework shows how a game designer can affect player's experience, but it is the player who crafts the gameplay experience.

A player needs to start with the experience crafted by the game in order to understand the mechanics of the game. And mechanics are built on top of two layers: hardware and software (see Fig. 2). As it is demonstrated in the following sections, video games can make different use of mechanics with hardware signifiers and software signifiers in order to invoke "gamic alienation."



Design of Alienation in Video Games, Fig. 1 MDA as seen by designer and player

In the next section, the first part of the continuum, *hardware signifiers*, is discussed (Fig. 3).

Hardware Signifiers

In first *Metal Gear Solid (MGS)* (1997), the game features a boss battle with an enemy called Psycho Mantis. No details about the character are presented before the encounter, except the clue in his name. When the player first confronts him, a cutscene intervenes the gameplay, and during that cutscene, Psycho Mantis starts to comment on the save files of the player, depending on which system the game is being played. If *MGS* (1997) is played on PlayStation, then Psycho Mantis will comment on Konami-based save files ("You like Castlevania, don't you?"). If it is played on Nintendo (which is called as *Metal Gear Solid: The Twin Snakes* (2004) and is the remake of the original game), then there are other specific games he is able to recognize, which are *Castlevania: Symphony of the Night* (1997), *Super Mario Bros.* (1985), *and Eternal Darkness: Sanity's Requiem* (2002). If there is no save file that the system can detect, Psycho Mantis says ("Your memory is empty"). Moreover, Psycho Mantis also comments on how many times the player has saved the game until that point of gameplay or how he is acting towards enemies in the game (e.g., using violence or stealth). After that, he orders the player to put his controller on the floor and he starts to move the controller by using vibration feature.

When this sequence is over, the player starts to fight with Psycho Mantis. During the fight, Psycho Mantis can lift all the items and objects in the room and throw them to the player's avatar, Solid Snake. All the attempts by the player to hurt Psycho Mantis are failed and the player loses all the control over the controller because of Mantis's psychokinetic abilities.

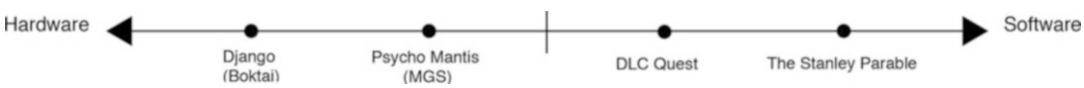
The only way player can defeat Psycho Mantis is to unplug the controller's cable from the console's port and plug into the second one. By switching the controller's port, player regains its control over Solid Snake and since Psycho Mantis cannot read her mind anymore, the player can easily beat him.

This instance of gameplay moment shows how mechanics can be used to create a "gamic alienation." Before presenting the actual challenge, an in-game character refers to non-in-game elements such as save data from other games, or explicit reference to the controller. This gameplay moment occurs at a point where player is already familiar with aesthetics and dynamics of the game, and by using hardware signifiers, the mechanics in the game encourage the player to question mechanics themselves and therefore, it requires a critical reflection of the medium. The game defamiliarizes player from the game itself.

This kind of alienation that makes use of hardware signifiers is also used in Nintendo DS game, *The Legend of Zelda: Phantom of Hourglass* (2007). One specific puzzle involves critical thinking and requires the self-awareness of the player in order to overcome the challenge. As it is known to all, Nintendo DS features two split screens. And in this puzzle, the player needs to press the seal on a map from upper-screen to bottom-screen. The player needs to close her DS and open it again in order to complete the task.

Another prominent example that makes use of this approach is *Boktai: The Sun is in Your Hand* (2003). A Game Boy Advance title directed by the designer of *Metal Gear Solid* (1997), Hideo Kojima, *Boktai: The Sun is in Your Hand* (2003)

Design of Alienation in Video Games, Fig. 2 The relationship between hardware, software and mechanics



Design of Alienation in Video Games, Fig. 3 A continuum to show the categorization of gamic alienation

introduces a vampire hunter called *Django* and the game asks the player to be outdoors and get sunlight. The game asks this because the game's cartridge included a daylight sensor (Plunkett 2017) and you can save the energy from sunlight in batteries and later, *Django* can use that energy for his weapon to play against his enemies in the dark. *Boktai: The Sun is in Your Hand* (2003) is simply another title that induces reflection on the game's medium. Even though the game explicitly mentions that only sunlight can be used to save energy, some players found out creative solutions to get sunlight without going outdoors (Plunkett 2017). This is just another proof that raising a critical approach via mechanics can lead to unexpected gameplay styles and offer different aesthetics.

Software Signifiers

In the previous section, the use of hardware signifiers within the context of "gamic alienation" is examined. The three titles that are covered demonstrated how mechanics can be used to refer to physical space outside game's world.

In this section, different approaches to create alienation with the use of software signifiers are identified, in particular through the reading of *The Stanley Parable* (2013). Unlike the examples that use hardware signifiers, *The Stanley Parable* (2013) has been selected since it provides a wide range of "gamic alienation" moments that are distinct than the ones already analyzed. In no particular order, these approaches created with the use of software signifiers can be listed as:

- Conflict between narrator's comment and player's actions
- Demonstration of game's production process
- Reference to other game worlds

Conflict Between Narrator's Comment and Player's Actions

Stanley Parable is an indie game that includes a voice-over narrator who tries to tell a story by commenting on the actions and the decisions taken by player. Unexpectedly, the game plays with narrative conventions in so far that in most of the cases, the descriptions of the narrator conflicts actions taken by the player.

The game starts in an office room and in the very beginning, the player finds himself in a room with two doors. The narrator tells that "When Stanley came to a set of two open doors, he entered the door on his left."

Evidently, it depends on the player to choose which door she wants to enter. Choosing right door breaks the narrative progression of narrator and tells the player to return back to her path. Otherwise, narration continues smoothly until to a certain point where something that narrator has not planned appears.

The conflict between narrator's comments and player's action is the first and major type of alienation effect used in *The Stanley Parable* (2013).

Demonstration of Game's Production Process

The second type of alienation in the game is about showing the scenes and assets behind the game's production process. There is one particular part in the game where a female narrator takes over and teleports Stanley to a museum so that he can explore the game's production process. In this museum level, player can see the credits, content from different endings, scale model of levels in the game, the details about Steam's Greenlight process, and the assets that was removed in the final version of the game. But this is rather an interesting use of alienation as these assets take place in the very final build of the game, even though they are claimed to have been removed. For example, in one of the rooms in the museum, player sees "Warzone" scene and it is written that:

> Early in development, we designed an ending where Stanley would end up on a battlefield fighting aliens. The action game would become sentient and would wage war against the Narrator. We realized shortly after starting to build it that it was far too jokey and on-the-no for the tone of the game.

Thus, players are essentially playing a level within the game where they are able to see behind the scenes of development and understand the

intentions of game designers. This level suspends the gameplay and playfully refers to its own artificiality by using software signifiers to create alienation effect.

Reference to Other Game Worlds

The third type of "gamic alienation" through the use of software signifiers can be described with the references to other game worlds. These references can either be visual analogies to game environments of other titles or replication of mechanics from other games.

The Stanley Parable (2013) accommodates levels from other titles such as *Minecraft* (2009) and *Portal* (2007). There is a special ending in the game where narrator gives up on player and instead of convincing Stanley to follow his orders, he loads example levels from *Minecraft* (2009) and *Portal* (2007), respectively.

Another title that serves as a good example to explain this category is *DLC Quest* (2012). The title of the game refers to Downloadable Content (DLC), and it is a satirical critique of games that promote DLC packages. *DLC Quest* (2012) does not incorporate the mechanics from other titles literally but alludes their implications within its own mechanics.

DLC Quest (2012) also includes DLCs, but unlike other games, DLCs in this game can be purchased freely. The game is based on a 2d platformer genre, but it starts without any animation or sound. A merchant in the first level is met, reminiscent of the ones in an RPG game, and he informs the player that he needs to collect coins to buy in-game components like sound, animation, enemies, and weapons. Obviously, the game aims to critically refer latest industry trends for monetization models used by triple-A studios.

Presenting game's essential components such as sound and animation as a separately sold DLC, required to be bought by the player to further progress in the game, elevates its meaning to a critical level. Hence, the player is considered as an active agent who has a background knowledge of the DLC issues. Although it is possible to play the game without understanding the self-referential messages implied through mechanics, it plays an important role to perceive software signifiers.

Conclusion

In this entry, the concept of alienation is examined through the reading of several games. The article initially draws inspiration from Brecht's alienation effect, but it is primarily based on MDA framework. The entry identifies two important terms: hardware signifiers and software signifiers. And games can be placed differently on this continuum.

The most important conclusion of gamic alienation is the games that use this effect want their players to take a critical stance towards the game itself and become self-aware. This is done by changing player's focus from the avatar's actions and events taking place on the screen and by drawing attention to game's mechanics, including the hardware that the game software is running on.

Nonetheless, there are issues that need to be addressed in a future research. First important point is that the use of gamic alienation does not always lead to critical play. Regardless of game designer's clear intentions, the gameplay experience can lead to hours of frustration among players, and it can eventually cause them to leave the game. It is worth analyzing why this issue occurs and how it can be addressed.

Secondly, the parameters to determine a game's place on the hardware/software signifier continuum are not clear. Further analysis is necessary to formulate the attributes of a game in the pursuit of improving continuum's structure. New categories can be introduced if necessary.

The results listed above are only limited to the reading of few games. As such, they are not exhaustive and therefore requires validation through empirical research and examination of a wider range of video games. In addition, new emerging technologies such as VR and AR provide more opportunities for using alienation effect in different ways. This entry shows the scarcity of good examples that make use of hardware

signifiers for creating gamic alienation. The findings in this entry can provide some insights on alienation concept and potentially inspire game designers to create new alienation effects.

Lastly, instead of purely focusing on immersion, video games can embrace the technical attributes it inherits as a medium and incorporate them to provide enriching play experiences. Just as Brecht wanted to encourage the audience to question the events on the stage, why don't the video games motivate players to be self-aware and take more action beyond the screen?

Destiny and Destiny 2, an Analysis of an FPS

Kyle McCarter[2], Brandon Coker[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Multiplayer first-person shooter; Video Games

Definitions

First-person shooter (FPS)= a genre of games where the camera focuses on a gun (or other weapon) where the objective is to eliminate specific targets.

Multiplayer First-Person Shooter (FPS)

Destiny is a multiplayer first-person shooter franchise developed by Bungie. *Destiny 1* was published by Activision, while *Destiny 2* was self-published by Bungie. *Destiny 1* was released for the Xbox 360, Xbox One, Playstation 3, and

Playstation 4 in 2014. *Destiny 2* was released for the Xbox One, Playstation 4, and Windows in 2017 while getting a Stadia release in 2019. The most recent expansion, Beyond Light came out in November 2020. All games are rated Teen.

Destiny's target audience is anyone who enjoys a science-fiction first-person shooter. The gameplay and mechanics are similar to other popular first-person shooters but with a little hint of difference when it comes to abilities. *Destiny 2* is similar to other first-person shooters, such as the *Halo* and *Call of Duty* games. It has the same basic controls, but the right bumper provides an extra method of attacking, usually a melee option.

The *Destiny* universe takes place in the Milky Way, several thousands of years after the present day. The bulk of the game takes place in a giant open world where the player travels from planet to planet trying to find the Vanguard, high ranking members of the same race as the player character, to rally together in hopes of reclaiming their home from the alien race known as the Cable, who are led by the warlord named Ghaul. In the beginning of the first game, they come to Earth and try to steal the Traveler's Light, who is a moon-sized god that granted the power of the light to humanity and its allies.

In terms of the HUD, there is a health bar on the top middle that only appears after the player takes damage. The bottom left lists of the player's ammo, grenade, melee ability, and super energy bar. The top left houses a radar (when available). Players can compete in several player versus enemy modes to earn loot. Loot ranges from common, uncommon, rare, legendary, and exotic. They all drop from enemies corpses form of an engram, which is a dodecahedron that is colored to show rarity. From the most common to rare the colors are white, green, blue, purple, gold/yellow. There are a few other ways to get rare loot, which include getting them from stories, bounties, quests, doing a raid which is the hardest player versus enemy quest players can do, or doing multiplayer. Engrams hold weapons or armor that players can use to upgrade their light level. Light level is a character's armor and weapon rating; basically how much damage they can take and deal to enemies. The player base spends a lot of time collecting armor and weapons; many hope to achieve to collect a full armory.

If there is a point of contention in *Destiny*, it would be their multiplayer matchmaking, called the Crucible in *Destiny 2*. In the first game, players could pick a game mode, but not a map. In *Destiny 2*, the player is unable to pick a game mode or map to play on. This leaves players who wish to only play one mode a bit out of luck; they have to hunt for a custom game and hope that they find a lobby that fits them if they do not already have a group of like-minded players.

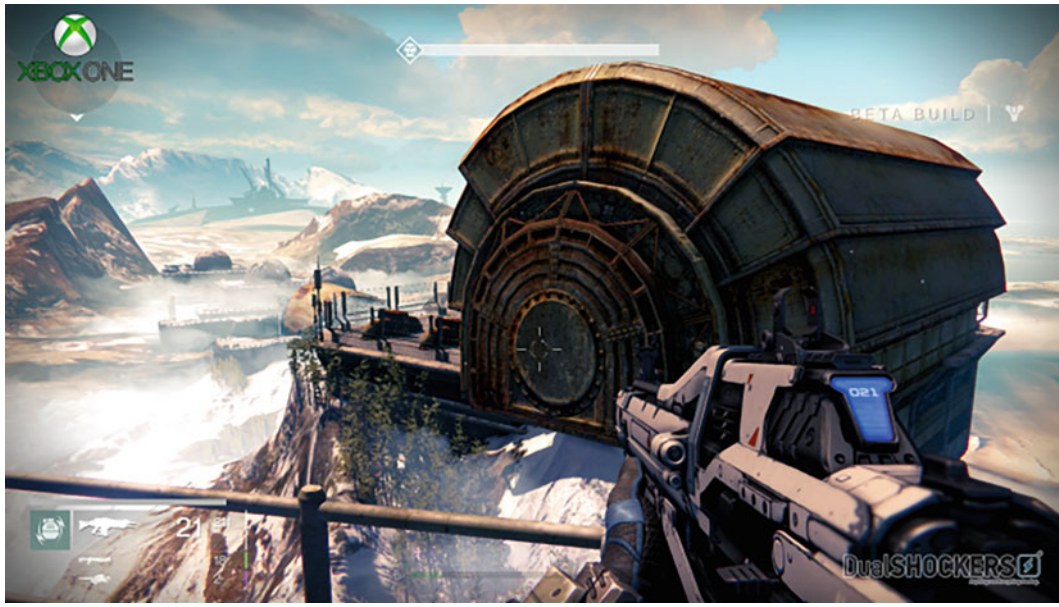
There is also one major controversy with the series: the DLC content and the game itself. In the first game, Bungie did not release the whole game right way. Instead they decided to slowly release it through DLC release. It was not until their final DLC that the game's mechanics were fully realized.

Some players believe that Destiny 2 is an improvement from the original Destiny, but some others opine that the original game is superior (Heather 2021 & Stevryu et al. 2017). To compare and contrast the two versions, we can examine the following:

1. Player Base: Although Destiny is very popular, Destiny 2 has a much larger player base with over 20 million players.
2. Weapons: Players can carry three weapons in both Destiny and Destiny 2. The major advantage of Destiny 2 is that all weapons are already fully leveled up, unlike Destiny where players have to spend time and resources to level up a weapon. Destiny 2 also provides more exotic weapons categorized into kinetic, energy, and power weaponry.
3. Story: Unlike the original Destiny, every story and plotline in Destiny 2 has a clear beginning, middle, and end.
4. Character Development: Both Destiny and Destiny 2 offer three character classes, namely, Titan, Hunter, and Warlock. In Destiny, players can customize the subclasses. In Destiny 2, customization is replaced by new special abilities for each character.
5. Armor: Destiny 2 allows customization of armor with mods and perks.
6. Content: Compared to the original Destiny, Destiny 2 has more worlds to explore, more

raids and dungeons, and more competitive modes like Gambit and Crucible.
7. Hybrid PvP/PvE: Destiny 2 offers a hybrid PvP/PvE mode that does not exist in the original Destiny.
8. Raids: Both Destiny and Destiny 2 require a team of six players to complete a raid mission. Destiny 2 provides additional Guided Games feature for solo players to team up with others to complete missions.

In conclusion, Destiny 2 is certainly an improvement over the original Destiny. Nevertheless, every player is entitled to his or her own



Destiny and Destiny 2, an Analysis of an FPS, Destiny 1 Destiny 1

Destiny and Destiny 2, an Analysis of an FPS, Destiny 2 Destiny 2

opinion as far as what game he or she likes the most.

Detecting and Preventing Online Game Bots in MMORPGs

Huy Kang Kim and Jiyoung Woo
Graduate School of Information Security, Korea University, Seongbuk-Gu, Seoul, Republic of Korea

Synonyms

Cheating; Detection; Game bot; MMORPG

Definition

Game users cheat to level up and accumulate cyber assets in an easy and fast manner without sufficient effort. One of the most widely used tools for cheating in online games is the game bot, which enables users to cheat in a convenient way by automatically performing the required actions. Therefore, game companies employ various security solutions for the detection and prevention of game bots.

Introduction

Online gaming is one of the successful Internet services. In the past few years, online games have become popular and have been generating huge profits. Online game companies generate profits by charging users a subscription fee and selling virtual items to them. Among the various types of games, MMORPGs (Massively Multiplayer Online Role Playing Games) make up one of the most popular genres.

As online games gain economic and social importance, various forms of threats emerge. A variety of methods have developed to parasitize and gain unfair advantages in online games. In this chapter, we focus on cheating actions using the game bot, which is one of the most prevailing reasons why users get banned from the game company.

Game users cheat to level up and accumulate cyber assets in an easy and fast way without sufficient effort. Game items and game money are critical to increasing the survivability of in-game characters by improving their power and reputation. In particularly, MMOPRGs are designed such that players take prescheduled courses to achieve high-level characters and become rich in cyber assets. These courses require the users to spend a considerable amount of time on repetitive play.

To skip these time-consuming processes for achieving high-level characters and acquire more cyber assets within a short period of time, users begin to cheat. One of the most frequently used tools for cheating in online games is the game bot. The game bot enables users to cheat in a convenient way by automatically performing the required actions. A typical game bot is an auto program that plays the game instead of a human.

Some users are eager to achieve a high level within a short period of time, so they buy virtual goods or higher-level accounts by paying real money. Game items and currency gained through game play can be sold and monetized into real currency. Real money trading of virtual goods is also one of reasons why players cheat. The illegitimate activity of gathering virtual goods in online games primarily for real money is called gold farming (Davis 2009). Gold farming is one of the most problematic issues in online games because gold farming is not only performed at an individual level but also by a factory-sized illegal group. “Gold farming groups” are industrialized organizations that gather and distribute virtual goods for capital gain in the online gaming world (Keegan et al. 2010). Real money trade by

gold farming groups has now become a social problem in many countries. Real money trade leads to tax evasion, illegal labor in developing countries, and damage to the game company. Gold farmers mainly use game bots for a large-scale operation, thus saving on labor costs.

Cheating in online games is no longer a personal problem of a player and causes damage to other players since online games maintain a massive set of players who form social relationships with other players.

Cheating causes an unfair competition, spoils other players' fun, and makes other players lose their motivation for the play. For example, bot users play the game much longer without a break, while playing continuously for a long time is difficult for human players. Since the activities and extraordinary abilities of game bots are noticeable to other players in the game world, they can make users feel that the game is unfair and cause users to leave the game. For companies, the detection and prevention of cheating incur a significant expenditure. When players use a game bot, they can reach the highest level in a shorter period of time than that expected by the game designers. Then, the users at the highest level have no more game contents to enjoy and leave the game. Consequentially, cheating causes various losses to the game company. It reduces the item sales amount, and eventually the number of players, and shortens the game lifecycle.

Online game companies realize the seriousness of the damage caused by a gold farmer group; they detect game bots and then ban their accounts or IPs to neutralize the gold farming group. They actively hire monitoring personnel, called GM (Game Masters), and deploy security solutions on both the client side and the network side. In addition, they adopt log analysis systems to detect game bot users.

Here, we will discuss some literature on state-of-the-art game bot detection and prevention methods, with the aim to fully understand the current prevention techniques and to advance countermeasures against the use of game bots in online games.

Literature Review

Technology Trends

Game bot detection methods have evolved over the years in the following order:

- Client-side detection and network side detection (first generation)
- Server-side detection (second generation)
- Surgical strike (third generation)
- Proactive detection (advanced surgical strike)

The first-generation methods are signature-based methods. Client-side bot detection including antivirus programs and CAPTCHA (Completely Automated Public Turing test to tell Computers and Humans Apart) is a first-generation method. The first generation of commercial products could be detoured with reverse engineering. In addition, CAPTCHA can annoy users.

The second generation is the server-side detection. This method mainly focuses on distinguishing between a bot player and a normal player by analyzing server-side log files. As gold farming becomes industrialized, the detection of all bot users is difficult to implement because of the huge number of bot users. It is not efficient because gold farming groups provide standby characters against being banned by the game company. Against the endless arm race battle between gold farming groups and game companies, we need a more efficient and selective detection method. The third-generation method is a surgical strike policy (Woo et al. 2011, 2013a, b). This method examines a gold farming group's ecosystem and performs banning to maximize the banning effect while minimizing the banning operation.

The current approaches in previous research rely only on the analysis of behavior patterns. When the players' activity patterns are distinguishable from the majority, these players are suspected to be malicious users. Most game companies take an action that bans bot users' accounts when they repetitively use a game bot.

Previous detection methods are reactive; they detect bot users only after users have repetitively exhibited malicious behavior. For a proactive and preventative response against malicious users, the social network analysis-based detection methods including the study on the contagion over the social network are used.

Client-Side Bot Detection Methods

Client-side methods are focused on signature-based, client-side BOT detection, such as anti-virus programs and CAPTCHA. PunkBuster (http://www.punkbuster.com) was the first attempt to avoid cheating on the client side. This tool monitors a client machine looking for any abnormality and sends a screenshot of the client to the game server. Khanh (2010) proposed a specifically designed module called GameGuard, which is added to the client to guard against possible cheating attempts from game players. GameGuard hides security-related modules so that hacking tools cannot see them, by using certain system techniques to interfere with some operations of Windows systems. It also places hooks in the Windows kernel mode to examine new processes entering the system and check whether these processes are hacking attempts or not.

CAPTCHA requests the answers that can be easily solved by humans but are difficult for bots to solve. Yampolskiy and Govindaraju (2008) proposed the integrated testing procedure as part of the game step performed by the player during the game in order to distinguish bots from legitimate human players. Golle and Ducheneaut (2005) demonstrated the CAPTCHA test embedding in the game world in order to minimize the disruption compared to the out-of-band use of CAPTCHAs.

However, the first generation of commercial products could be detoured with reverse engineering. In addition, the client-side solution has other drawbacks. Client-side solutions run on the client computer. This causes a load on the client computer and can cause any inconvenience to users. CAPTCHA can annoy users when they receive questions while they are playing.

Network-Side Detection Methods

Network-side detection methods are designed to look into network traffic or network packets generated by the client when the client communicates with the game server. This type of method detects network traffic burstiness and anomalies in the command timing, response time, and traffic interval. Some methods are designed to detect different reactions of humans and game bots to changes in network conditions such as protocol changes or the occurrence of traffic lags.

When a company changes its network protocol, game bots lose their connection and pause to update their programs so that they can be fitted to the changed protocol. When a company generates a traffic lag by design, human players react to the change sensitively, for example, by continuously clicking their mouse or keyboard buttons until the connection resumes, whereas game bots are not sensitive.

The network-side solution to a nonclient bot is to ask a question to the user who can give a right answer when she uses the client software provided by the game company. The nonclient bot does not operate on the client software, so it cannot provide the right responses for specialized questions.

Similarly, most network-side solutions mainly adopt a method that frequently changes the network protocol or applies cryptography to encrypt/decrypt network transmission.

For the P2P game, the game company facilitates a method for participants to reach a consensus on the current state of the game in a way that prevents malicious individuals and groups from cheating. Securing the protocol that delivers messages when peers communicate is a solution to this security issue.

The NEO (GauthierDickey et al. 2004) protocol is designed to prevent protocol-level cheating in P2P games. This protocol enables to accomplish the exchange of update information among players in an authenticated manner. It verifies the identity of the sender and registers updates in advance to ensure that every party has chosen its update for a round before it may read the updates of the other players. It also attempts to ensure game state consistency by confirming which

updates have been received by which peers. The details of the NEO protocol (Hu and Liao 2004) are as follows: It divides the time into uniform intervals, called rounds, in which each player sends an update to all the other players. Each update is encrypted, and in the following round, the players send the corresponding key to each other.

Corman et al. (2006) invented a more secure protocol called SEA (Secure Event Agreement). The authors investigated the drawback of the NEO protocol and then proposed an improved version of this protocol. They focused on the protocol for communications rendering information such as the position, direction, and action of virtual entities. The SEA protocol signs an entire event message and binds the message to a particular round and group.

Most of the network-side countermeasures are based on a cryptographic methodology to guarantee network traffic integrity and confidentiality. To secure network traffic, it is necessary to encrypt and decrypt the packets. However, this requires a considerable amount of computing power, and the error in this process can spread to all concurrent user connections. This can cause single-point-of-failures, so game companies are reluctant to adopt strong network-side cryptographic methods.

Server-Side Detection Methods

Server-side methods use the log collected in the server of the company. The company records user behaviors as a log in the database. Game bots display repeated and biased patterns in their actions differing from human players. Technically, server-side methods adopt data mining-based or statistics-based methods. First, these types of methods extract the feature set from the log. Then, classification using the feature set is performed; classifiers are automatically built through learning from data by using data mining or statistical methods.

Feature extraction is a critical component of behavior-based detection techniques. First, we build a taxonomy of behavior-based features that classifies previous research in a systematic way. Then, we review previous works based on this taxonomy.

User behaviors in the gaming world include major activities such as move and play. Other socializing behaviors are also a good source for game bot detection. MMOPRGs are designed to make people interact with others in order to complete difficult tasks and then level up their characters and have fun playing the game through such interactions. User behaviors can be categorized into sole behaviors and social behaviors. The main sole behaviors are movement and play. In MMORPGs, a play encompasses combat, harvest, and healing. Social behaviors mainly include party play, communication, trade, and community activity.

- Party play means that two or more players form a group to undertake quests or missions together. Users in party play typically share experience points, money, and items acquired upon completion of successful quests. Most MMORPGs are designed to require party play.
- Players in the game communicate with other players by sending text messages or e-mails. In the gaming world, players can trade items. In general, players exchange items with other items of equivalent value or money. Trade patterns provide a good clue to detect abnormalities, particularly gold farming groups.
- In general, players maintain a friend list for easy co-play and communication. Player A sends a friend request to player B. When player B accepts the request from player A, they become friends. They show up in the friend list of the other party.
- Players organize a guild to socialize or achieve a similar long-term goal.

Previous works focused on movement patterns and sole play patterns because they used simulation data obtained by operating game bots. This is an alternative method used when a real game log is not available. Bots are programmed, so their movement and play patterns are repetitive and regular. Bot detection models have been proposed based on this fact. Social behaviors have recently been adopted in research. Social

behaviors cannot be obtained in the absence of the cooperation of a game company. Fortunately, several studies provide the analysis results of large-scale real data under the cooperation with game companies.

Now, we will review key papers in detail.

Movement-based methods use the fact that most bots have preconfigured moving behaviors while humans have random moving patterns (Kesteren et al. 2009; Mitterhofer et al. 2009).

- The longest common path (LCP) is a good indicator that measures the regularity in movement patterns. Bots take same paths repetitively, so they have high LCP, while human players show random behavior and thus have low LCP. Furthermore, bot users can turn the bot program on and off, which results in a high variation in regularity. Human players will have low regularity and a low variation in regularity.

Play patterns are widely used for distinguishing between a bot behavior and a human behavior.

- Chung et al. (2013) considered all types of behaviors that can be observed in the game world. They categorized play patterns into Battle, Collect, and Move; specified battle behaviors as Hunting, Attack, Hit, Defense, Avoidance, and Recovery; and built a feature set by using such specified behaviors. The features can be directly retrieved from the game log. Further, they developed the feature set from raw features in order to represent how efficiently a user plays the game. The developed features include combat ability, collecting pattern, and movement pattern.
- Christensen et al. (2013) examined the race duration from both the client side and the server side, and the gap between the duration measured on both sides. They suspected a very short duration time, long duration, and inconsistent duration time between the client side and the server side.
- Platzer et al. (2011) analyzed the sequence of play patterns and identified the differences in the sequences of bots and human players. Since bots can make restricted choices when they play the game, they show limited and repetitive behaviors. The authors implemented their proposed detection tool on a server-side and client-side instance and an in-game client-side add-on that is capable of monitoring its own event horizon.
- Lee et al. (2014) proposed a measure that expresses the extent to which a player behaves repetitively. They analyzed the full action sequence of users on a big data analysis platform. The differences between the action sequences of normal users and bot users were determined.

With respect to social behaviors, party play, communication, and trade have been explored to identify the differences between game bots and human players.

- Kang et al. (2013) focused on party play, which is a group play with several characters, for game bot detection. They pointed out that the game bot forms a party play with a limited number of players, usually other game bots, and has limited actions biased towards collecting game money in the party play.
- Kang et al. (2012) proposed a chatting-based bot detection model. They retrieved chatting contents and derived features by using text mining techniques from the chatting contents. They also derived entropy-based features, chatting-pattern based features, and text features. The proposed detection model assumes that game bots communicate with other bots through limited messages that humans find difficult to understand.

To detect factory-sized illegal groups that operate numerous game bots, i.e., gold farming groups, an understanding of the ecosystem of a gold farming group with respect to the trade patterns is required. The followings are some surgical strike approaches.

- Woo et al. (2011) and Kwon et al. (2015), respectively, identified the ecosystem of gold

farming groups, as shown in the following figure. Gold farmers repeatedly hunt monsters and harvest craft materials to earn game money and to save time. The collected items and game money are delivered to the merchant characters; merchant characters then sell these items for game money. The game money from gold farmers and the acquired money by the item trade through merchant characters transfer to banking characters. Banking characters possess most of the game money in the GFG to sell the game money efficiently.

- Ahmad et al. (2011) considered player characteristics and items and detected contraband networks in terms of players and items. They analyzed clandestine social networks of deviant players in MMOGs (Massively Multiplayer Online Games) along with a network of contraband items sold by these players.
- Oh et al. (2013) utilized the fact that game bots and human players form social networks in contrasting ways. They constructed a social network on the basis of mentoring relationships. They derived features from the play and the trade and added social network-based features. These authors proposed new features based on eigenvector centrality to capture the social influence.
- Keegan et al. (2010) and Ahmad et al. (2011) studied the clandestine trade and trust networks of gold farmers, respectively, and described how gold farmers try to obfuscate their interaction patterns in these networks to evade detection.
- Keegan et al. (2011) discussed the usefulness of studying clandestine networks in the virtual world and their applications to studying their counterparts in the offline world.
- Blackburn et al. (2014) introduced an interesting platform, the Steam Community, an online social network built on top of the world's dominant digital game delivery platform. They performed a thorough social network analysis on the players' social relationships and interactions. They found that the cheaters' network position is largely indistinguishable from that of fair players.

More advanced methods are based on the contagion process in the players' social networks. This generation method is in an early stage.

- Woo et al. (2013a, b) and Blackburn et al. (2014) showed that a social contagion of game bot usage can develop. The first and the third study showed that contagion between players in a social network exists. The second study proposed a modeling method to track the contagion process. This modeling method is based on an epidemic model. Modeling of the diffusion process enables one to predict the future diffusion process and to estimate the likelihood of an individual's bot adoption.
- Ahmad et al. (2013) proposed label propagation to detect gold farmers. The proposed model initially sets the label that indicates the gold farmers, and then, propagates these labels over highly connected networks, such as the mentoring network, housing-trust network, and trade network. To reduce false positives in which normal users are misjudged as bot users, the authors also considered user similarity.

The game company adopts a negative policy for bot users since banning accounts often causes a legal issue between the user and the game company. If the game company selectively targets users for banning, it can ban users for minimizing the compliance risk and maximizing the banning effect at the same time. Identifying influentials in the diffusion process of game bot usage will solve this issue.

- Ki et al. (2014) provided the analysis results on a contagion of game bot usage and identified the influentials in the contagion process. Identifying the influentials in the diffusion of malicious behaviors and understanding the diffusion process of the malicious behaviors is particularly important, as it will give the game company a new opportunity to act proactively and preventively against malicious users.

Conclusions

This survey summarized how the game bot detection methods have evolved in the recent years. It further developed a taxonomy according to the data source for countermeasures and introduced the state-of-the-art literature on the game bot detection and prevention methods. The game bot detection methods have been developed from client-side detection and network-side detection methods to server-side detection methods. Client-side security solutions that are required to be installed on the client computer often cause collisions in the operating system, resulting in user inconvenience. Network-side detection methods such as network traffic monitoring or network protocol changes cause a network overload and lags in the game play, a significant annoyance in the online gaming experience. Server-side methods that are mainly based on log mining of user behaviors produce highly accurate rate and effective rules to detect game bots and do not interfere with the game play. With the evolution of game bot usage, from being used by individual users to gold farming groups, server-side methods have been advanced to detect gold farming groups. Further, the detection methods have become more proactive, getting hints from the contagion process of the game bot usage on a social network that can be observed in online games.

Through this survey, several research gaps have been identified.

First, the surgical strike methods for the detection of gold farming groups have not been explored sufficiently thus far. As gold farming increases, efficient and effective detection methods are needed and the current literature has much room for improvement.

Second, the server-side methods mostly focus on feature extraction and apply existing machine learning algorithms to build automatic classifiers. However, an algorithm specialized for game bot detection has not been developed thus far. An algorithm that reflects the characteristics of game bot users or gold farming groups may be more effective than the existing algorithms.

Third, game bots are evolved to avoid detection, so behavior-based methods become outdated in a short span of time. More features that reflect the cheater's psychology and the behavior lifecycle can be used for generating more genetic models. In addition, behavior features are generally game-specific, so generic features also should be considered.

This survey will hopefully boost researchers' interests in this area of study, help in determining the research agenda, and finally, lead to the development of countermeasures against game bots.

Digital Games for Animals

Mikhail Fiadotau
Centre of Excellence in Media Innovation and Digital Culture (MEDIT), Tallinn University, Tallinn, Estonia

Definitions

Digital games aimed at animal players are a growing area in both entertainment and research, enabled particularly by the mass availability of touchscreen technology. These games rely on animals' natural proclivity for play and can facilitate playful interactions between species.

Prerequisites for Digital Play in Animals

Humans are far from the only species known to engage in playful behavior. Wirman et al. (2011) argue that "all mammals play, including humans," and play-like behaviors have also been identified in birds, reptiles, fish, and invertebrates such as octopuses (Burghardt 2005). While the evolutionary dynamics and psychological mechanisms of play are not yet fully understood, it is known that in both humans and other animals, playing is a crucial prerequisite for physiological, psychological, and social development (Bekoff 1972) and play deprivation can result in serious developmental deficiencies in adulthood (Hol et al. 1999). Based on this evidence, scholars such as Sutton-Smith (1997: 218) have advocated for a definition of play which encompasses both humans and animals.

Animals are also known to interact with technology in a variety of ways. Many pet owners have observed their animal companions watch television, and animals' engagement with screen media can be meaningful. Research suggests, for example, that dogs can recognize other dogs on the screen and distinguish them from other species using visual cues alone (Autier-Dérian et al. 2013).

Service animals are often trained to use technology. One example is "canine augmentation technology," developed to foster more efficient dog–human communication in search and rescue operations (Ferworn et al. 2006). Digital technology also plays a major role in animal cognition research, with great apes such as the male bonobo Kanzi being trained to use a touchscreen interface to communicate with humans in a lexigram-based language (Greenfield et al. 2008). More recently, underwater acoustic touchscreens have been developed to facilitate human–dolphin communication (Herzing 2016).

Digital games for animals use technology as a vehicle for animals' natural playfulness.

Examples

Whereas some digital games for animals are commercial products targeting pet owners, others are

developed for research purposes or for use in specialized facilities such as animal rehabilitation centers and zoos. Of the former variety, most games appear to target cats and feature a similar mechanic: tracking and tapping an object moving on the touchscreen. *Friskies Jitterbug* and *Cat Alone* are the better known of many such titles. A number of similar games, such as *Jolly Dog*, also exist for dogs.

Research-based games and games used in specialized settings often focus on enriching the lives of captive animals, targeting species as diverse as parrots (Woodman 2014), penguins (Westerlaken 2017), and orangutans (Webber et al. 2017). Many such games promote cross-species play. One example is *Pig Chase*, an experimental game developed in the Netherlands, which involves farm pigs interacting with a large touchscreen installed in their pen. The objective is for a pig to use its snout to touch a moving ball, which is remotely controlled by a human player. When touched, the ball fires off colorful sparks. The game keeps track of each pig's individual performance and has a leaderboard which can be viewed by the human on their tablet. The aim of the project is to relieve the pigs' boredom, which is a major issue in intensive farming, as well as facilitate cross-species play and, through it, reduce "the distance between farming practices and the general public" (Meijer 2016: 71). Other examples of cross-species digital play have involved orangutans (Wirman et al. 2011; Webber et al. 2017), cats (Westerlaken and Gualeni 2014), dogs (Wingrave et al. 2010), and hamsters (Cheok et al. 2011).

Rationale

One of the main reasons to explore digitally mediated play in animals is its potential to improve their lives. Digital games can provide cognitive stimulation and enrichment to captive animals, mitigating the issue of boredom and facilitating cognitive development (Baskin and Zamansky 2015). Experimental evidence suggests playing digital games can relieve stress and depression in home alone dogs (Geurtsen 2014). Another issue digital play can address is animals' sedentary lifestyle (Pons et al. 2014). One example is *Feline Fun Park*, a game for cats which has an automatic mode where the level of challenge is adjusted based on the animal's activity level (Young et al. 2007).

Digital play can also benefit human–animal interactions. Some digital games, such as *Canine Amusement and Training*, are designed to facilitate dog training (Wingrave et al. 2010). Other digital games, such as the human–orangutan collaborative game deployed at Melbourne Zoo, aim to increase visitors' empathy for animals while providing the latter with environmental enrichment (Webber et al. 2017). Another project, *Apps for Apes*, included an iPad donation campaign for captive orangutans as a way of raising public awareness about orangutan survival in the wild (Smith 2011).

As an area of research, digital play in animals can be regarded as part of the wider domain of animal–computer interaction (Baskin and Zamansky 2015) whose aims and concerns it shares. These include improving animals' life expectancy and quality, assisting working animals in their legal functions, deepening our understanding of animal cognition, and fostering better communication between species (Mancini 2011). Studying animals' digital play may also help us better understand the psychology and the roles of play – including in our own species (Wirman 2013).

Challenges

Despite their potential, digital games for animals present a number of challenges and concerns, most notably of an ethical nature. Play is meant to be a voluntary and autotelic (intrinsically motivating) activity (Denzin 1975), yet this is not always the case with digital games for animals, which in many settings are reward-based (Wirman et al. 2011). It is thus often unclear whether the animal is genuinely playing or exhibiting trained

behavior (Baskin and Zamansky 2015). Some breeds of dogs display strong predatory patterns when engaging with digital games, suggesting the animals may be trying to hunt, with the failure to capture the prey resulting in frustration (Baskin et al. 2015).

Another concern is the short- and long-term physiological and behavioral effects of digital play in animals (Westerlaken and Gualeni 2014). As many other aspects of animals' technology use, these require further research.

A more technical challenge lies in the fact that modern technology is overwhelmingly designed for human use and is not easily accessible to other animals. Most mammals, for example, have dichromatic color vision, as opposed to the trichromatic vision in humans (Neitz et al. 1989), meaning that they are able to distinguish between a more limited range of colors. Avians such as parrots can recognize images on a flat-panel display but not a cathode-ray-tube screen, due to the latter's flickering (Woodman 2014). Many animals, including dogs and cats, also have a different field of vision and depth perception compared to humans (Pons et al. 2017), making standard tablet screens suboptimal for their use. Additionally, most touchscreens are neither durable enough nor responsive to claws, rendering standard tablets nearly unsuitable for cat and dog use (McGrath 2015), despite the proliferation of "feline" and "canine" games on these devices. Thus a crucial challenge when designing a digital game aiming at animals is to ensure it uses "species appropriate" (McGrath 2009) technology and undergoes sufficient user testing with actual animals to mitigate the developers' inevitable anthropocentrism (Westerlaken and Gualeni 2014).
